Of course, one of the ways of studying the function of an organ is to observe the effects of the removal of the organ in question. On this basis we derive only meagre information as far as splenic function is concerned. Both animal experimentation and observation on the human subject show that clinically, splenectomy, when performed for injury, and in early life, does not affect the growth; nor does it necessarily interfere with pregnancy and childbirth; nor does it have any permanent effect on the general health of the adult, except perhaps that it produces a somewhat lowered resistance to infection, although the latter contention is open to argument.

As to the immediate effect of splenectomy. We are indebted to the careful work of Pearce, Krumbhaar and their associates for much of our information on the physiology of the spleen and what follows its removal. Physiologically, splenectomy mainly produces certain changes in the blood which cause a temporary anemia, an increased resistance of the red blood cells to hemolysis and a reduced tendency to jaundice, which, according to Pearce, is associated with the anemia of splenectomy. Moynihan, on the other hand, attributes it to the loss of ability of the spleen to send what he calls effete iron to the liver. The latter organ thus loses its ability to elaborate properly combined iron for the production of bone marrow and for hemoglobin formation. The reduced tendency to jaundice is also explained by the fact that after splenectomy the destruction of red cells takes place chiefly in the bone marrow, so that the products of disintegration, having a longer route to travel to reach the liver, arrive there in a less concentrated form than when coming from the spleen, so that it requires a much greater increase in hemolysis to reach a state of concentration sufficient to produce jaundice. Jaundice, according to this theory, "would be an index to the *site* of red blood cell destruction rather than its *degree*."

Splenectomy also causes an increased excretion of iron, a decrease of fat in the feces and an increase of fat and cholesterin in the blood, the last named being thought to aid the resistance of the red cells to hemolytic agents. In the course of time, the bone marrow also changes from its normal yellow fatty character to a red cellular hyperplastic type.

It is an interesting fact that any splenic tissue left in the body after splenectomy rapidly increases in size, indeed, reformation of splenic tissue equivalent to a normal spleen in size and appearance has been observed in from fifteen to eight and even less years after removal of the spleen for injury. A compensatory enlargement of lymphoid tissue throughout the body has also been noted. There is an increase in the number of endothelial cells in the lymphoids, which upon administration of hemolytic immune serum may help in the destruction of red cells. A similar phagocytic effect takes place in the Kupffer cells of the liver, suggesting a compensatory function in the liver as well as in the lymph nodes.

This brief outline of some of the changes that follow splenectomy in a measure explains the results of the operation *per se*. We see from it that anatomically and physiologically the spleen apparently derives its importance mainly from its connection with other organs, particularly the liver, which is said to receive

*Read before the Detroit Academy of Surgery, Detroit, June 19, 1925.

Copyright, 1925, by A. R. Elliott Publishing Company.

about thirty per cent. of the blood supply of the body and this directly from the spleen. It is easily conceivable, therefore, why a pathological process in the spleen produces serious interference with liver function and with the constituents of the blood.

We all know that the gross outstanding features of splenic disease are anemia and enlargement of the spleen, and it is no less a matter of common knowledge that splenectomy may and often does establish a clinical cure in certain diseases of the nutritive system, especially of the liver and the blood. The most important of such diseases that carry with them indications for splenectomy are, hemolytic jaundice, particularly the acquired type, splenic anemia in its various forms and stages and sometimes pernicious anemia. A recent addition to this list is purpura hemorrhagica of the thrombocytopenic type.

In pernicious anemia it is only in the early stages that splenectomy offers palliation and occasionally a supposed cure; and again in the rapidly progressive case with marked hemolysis it may be undertaken as a last hope, when everything else has failed.

In the acquired form of hemolytic jaundice and in the splenic anemias the operation has come to be one of distinct value. The relationship between hemolytic jaundice and disease of the liver and gallstone disease is well recognized. The tendency to the formation of gallstones in these cases is explained as being due to the viscosity of the bile, caused by overloading the liver with blood pigment set free by destruction of numerous red cells by the spleen. The remote results of this are seen in the development of cholangitis and finally cirrhosis of the liver. This once more illustrates the interdependence of the organs in the human body. There is also a close relationship between acquired hemolytic jaundice and the jaundice of biliary cirrhosis, in which splenomegaly and anemia also form part of the syndrome. Splenomegaly is nearly always associated with cirrhosis of the liver. The splenic enlargement, in fact, may be palpable before involvement of the liver is recognized. Nevertheless, it is generally conceded that the splenic enlargement is in all likelihood secondary to the pathology in the liver, both of which are probably due to the same factors. In cirrhosis of the liver splenectomy not rarely brings about marked improvement, although the exact reasons therefor are not definitely known, except that perhaps removal of the spleen effects a definite reduction in the quantity of blood brought to the liver. Owing to this well known recuperative power, the liver, though damaged, is thus able to resume enough of its normal function to bring about at least symptomatic relief.

It has been found that in chloroform poisoning the liver is fairly uniformly involved, consequently, if a section is removed it will be representative of the liver as a whole. Whipple found he could destroy about one third of the lobule with chloroform. This means that approximately one third of the liver had undergone necrosis. So great is the recuperative power of the liver, however, that in ten days to two weeks a section removed showed complete restoration of the liver lobule. This means that there was a growth of perhaps 150 grams, in a moderate sized dog in two weeks, a rather extraordinary healing power.

On the other hand, the enlargement of the spleen in certain cases of cirrhosis of the liver may be, not primary, but secondary to congestion. The question of removal of the spleen in these cases then becomes more a question of reducing congestion from the spleen to the liver and conversely, from the liver back into the spleen, than does removal of the spleen for the production of actual cirrhosis causing noxæ in the spleen. A certain number of clinical reports seem to justify this removal from whatever viewpoint it is observed. The exact relationship, however, awaits further investigation. It might be suggested that many of the cases of splenomegaly, with or without cirrhosis of the liver, are possibly phases of one and the same condition, and that the numerous names which at present are given to certain symptom-complexes are merely a cloak for our ignorance in a way similar to that in the days when jaundice was considered a disease and not a symptom, as we consider it today.

Most of the blood going from the spleen, the stomach, duodenum, and upper jejunum is sent to the left lobe of the liver; most of that coming from further down goes to the right lobe. This is because of the fact that the splenic vein meets the superior mesenteric vein at a right angle and that the main trunk of the portal vein is quite short before it divides into the left and right branches. Just as the Mississippi is half muddy for a considerable distance below where the Missouri empties into it, so most of the blood coming from the splenic vein remains on the left side of the portal vein and thus is sent into the left lobe of the liver. It is an old, well known fact that many cirrhoses of the liver begin in the left lobe, and that even in later stages the left lobe in many cases is far more fibrous and involved than the right lobe. It seems fairly reasonable to assume that perhaps the blood supply determines this change, if so, perhaps the spleen is really primarily at fault in helping to produce the cirrhosis, thus justifying the removal of the spleen, especially when it is somewhat enlarged.

In Banti's disease splenectomy has proved to be the only rational treatment, so that the indications for the operation in this disorder require little discussion. The fact that a few cases after the lapse of a number of years show signs of recurrence is, of course, no argument against the operation.

But the operation is not a simple one, the technical difficulties are such as to make it a serious procedure. This is due mainly to the presence of adhesions and the thin sclerosed and often calcareous vessels in the pedicle of the spleen, particularly in the advanced stages of the disease. The capsule of the organ is easily torn, and the pulp is soft and friable. Careful manipulation is therefore necessary. The operative mortality at first in the early days of splenectomy was as high as thirty-eight per cent., but in recent years the figure has been reduced to about eight per cent. or less. This satisfactory reduction in operative mortality is not only due to the perfection of the technic, but to proper preoperative treatment. In some instances x ray and radium treatment has been used to reduce the size of the enormously enlarged spleen, but in most instances preoperative blood transfusion has been the main contributing factor to the safety of the operation. In the Lankenau Clinic preoperative blood transfusion is resorted to in all cases

where the hemoglobin is below forty per cent., and is done about forty-eight hours before operation. Of course, the cardiovascular and renal functions are studied as a routine measure.

The approach to the spleen will depend upon the presenting conditions. Unless the spleen is enormously enlarged, the pedicle may be reached from the front, after the stomach has been drawn well to the right and the gastrosplenic omentum has been divided. The vessels in the pedicle are usually most conveniently reached by turning the spleen over, after releasing adhesions and dividing the splenophrenic fold of peritoneum. These adhesions, however, are often dense and may contain large veins which will have to be divided between large clamps, and the spleen gradually mobilized; venous oozing being controlled by hot gauze packs in the splenic bed. The hand is then introduced between the spleen and the diaphragm, and the spleen is drawn into the wound and turned over, the vessels in the pedicle are secured between clamps and cut as close as possible to the spleen. At this stage of the operation great care must be taken to avoid injuring the pancreas. Enough of the tissue of the pedicle must be left to allow the vessels to be ligated. The ligatures are applied separately to each of the vessels as they are identified. As soon as the bleeding from the pedicle has been controlled, the packs are removed, and after checking any bleeding in the subphrenic space the abdominal incision can be closed. If the operation is done for hemolytic icterus, it cannot be considered complete without careful exploration of the biliary passages. As we have already indicated, gallstones are present in about sixty per cent. of cases of hemolytic icterus, so that a splenectomy cannot be considered complete without exploration of the bile passages, and if the patient's condition permits, removal of the gallbladder, if such is indicated. Prophylactic appendectomy should also be done.

Postoperative transfusion of blood is often necessary. The greatest dangers after the operation, aside from shock and collapse due to the severe hemorrhage, are bronchitis and pneumonia, which with painstaking care are avoidable in most instances, particularly if the operation is done under gas and oxygen. One of the late complications to be feared is intestinal obstruction due to adhesions of the jejunum to the splenic stump or to a raw surface in the subsplenic space.

The remote results of splenectomy are, on the whole, excellent. In most cases a clinical cure is established, although examination of the blood oftentimes shows a permanent increased fragility of the red cells. Pernicious anemia is not always considered amenable to surgery, but in a certain type of cases the operation undoubtedly prolongs life and is followed by longer remissions of the disease.

SPLENECTOMY IN PURPURA HEMORRHAGICA

In recent years splenectomy has proved of distinct value in the treatment of purpura hemorrhagica. This is one of those diseases with which we are familiar but about which we know very little. It is only with the aid of modern methods of blood examination that a differentiation of the several types of the disease has been made possible. The type which seems to be amenable to splenectomy is the one known as essential thrombocytopenic purpura hemorrhagica. To Brill and Rosenthal of the Mount Sinai Hospital, New York, belongs the credit, in this country, of differentiating and naming this disease. As the term indicates, it is marked by a decrease or absence of thrombocytes or blood platelets in the blood.

It was Frank, of Berlin, Germany, who, in 1916, first offered the theory that the spleen inhibited the formation of blood platelets. Following this Kaznelson (in the same year) asserted that the spleen brought about the actual destruction of the blood platelets in this disease. Acting on this theory he proceeded to remove it with gratifying results. Since then the operation has been reported from many centres with equally good results.

It is well to bear in mind, in this connection, that up to the present time this thrombocytopenic type is the only type of purpura hemorrhagica for which splenectomy is indicated. It is essential, therefore, that the diagnosis is correct before venturing on surgical treatment for this form of hemorrhagic disease. A careful count of the platelets by one of the newer methods should distinguish this condition.

The Permanency of Hay Fever Cures

WILLIAM SCHEPPEGRELL, A.M., M.D.
New Orleans, Louisiana

The modern treatment of hay fever, as practised by the use of pollen extracts to desensitize patients from the pollens responsible for their attacks, is considered by most immunologists as being only of seasonal benefit.

In the clinics of the department of hay fever and asthma of the Charity Hospital of New Orleans, in which the attendance is over one hundred during the hay fever season, the permanency of cure of the cases treated is the most indefinite of all the statistics (1). This is due to the fact that these patients attend the clinics as long as they suffer from hay fever, but discontinue when this is not the case. Whether, however, such a discontinuance is due to inability to attend, or to a permanent cure, it is impracticable to determine.

In private practice, however, in which there is a more personal relation with the patients, information of the permanency of the benefit obtained by this treatment is not so difficult to obtain. A number of these cases will therefore be selected from this list, in order to illustrate that in a certain number of cases, at least, the treatment of hay fever is followed by a permanent cure.

Cases of cure lasting more than one season are not infrequently met with in the clinics. It is not unusual, for instance, to have patients report that they had received treatment before, and did not have hay fever the following year, and therefore did not report for further treatment. The present report is limited to cases in which the freedom from hay fever symptoms continued for at least three or more years.

Case I.—The first on this list is a cotton planter, forty-six years of age, referred by Dr. William Brickel, who had suffered for twelve years from a violent form of fall hay fever, and who was treated in 1913. During the months of September and October he was practically unable to visit his plantations, and when circumstances made this necessary he suffered from such violent paroxysms that he was incapacitated for days afterwards. He gave a marked reaction to the common ragweed, and was given a coseasonal treatment of pollen extracts in 1913, and complete preseasonal treatment in 1914 and 1915. The first treatment was of benefit, and the second and third apparently gave complete relief.

I did not see this patient until three years afterwards, when he reported that he had continued to have relief, and was able to visit his plantation without discomfort. Since then I have had reports from him from time to time, each confirming the record of a permanent cure.

Case II.—The next case is that of the manager of a manufacturing plant in New Orleans, who was referred by Dr. Peter Salatich on April 2, 1917. The patient was fifty-one years of age, and had suffered for thirty-eight years from hay fever, which developed during the months of April and May, and August, September and October. During the last two years the fall attacks had been followed by asthma. He gave a sixty per cent. reaction to the grasses, and seventy and seventy-five per cent. to the common and giant ragweeds, respectively. He was given a course of treatment in 1919 and 1920, including desensitization first to the grasses, and then to the ragweeds, the treatment being repeated in 1920. Since that time the patient, whom I have occasion to see at intervals, has had no further attack of either hay fever or asthma. On August 15, 1924, he reported to the office, fearing that he had a recurrence of his hay fever, but this proved to be only a coryza, which disappeared in a few days.

The ten year old son of this patient had bronchial asthma in 1920, which was found to be due to pollen sensitization. The treatment of this case was also followed by a permanent cure.

Case III.—Permanent results were obtained in the case of a stenographer thirty-two years of age, who had suffered for three years from perennial hay fever. She was found sensitive to the grass, chenopod, and ragweed groups. She was also sensitive to face powders, feathers, and wool. The elimination of these resulted in improvement, but the relief was not complete until she was desensitized to the three pollen groups. The patient has had no recurrence since 1918.

Case IV.—The wife of a well known physician applied for treatment on June 20, 1918, having suffered from hay fever for two years, the period being May 15th to November 1st. She had sixty-five per cent. sensitivity to the grass group, and seventy per cent. to the ragweed group. She was given a coseasonal treatment for the spring hay fever and preseasonal for the fall hay fever. This resulted in complete relief, which has been maintained since 1918.

Case V.—A prominent druggist of Mississippi applied for treatment October 1, 1921, being referred by Dr. T. R. Beech, of Ellisville, Mississippi. He suffered from hay fever in the spring and fall, but attacks could also be excited at any season by the inhalation of the dust of flaxseed, when handling this in the course of his business. He was twenty-six years of age, and had suffered for five years. He presented a reaction of fifty per cent. to the grasses, and thirty-five per cent. to the ragweed group. A course of desensitization was outlined, which was carried out by Dr. Beech. This was followed by complete relief, the patient having had no recurrence of his hay fever.

Case VI.—A patient forty-three years of age, suffering from hay fever for two years, was referred to me by Dr. J. H. Slaughter, of Bogalusa, Louisiana, on July 15, 1920. The attacks lasted from April to October, and the patient showed a sensitivity to the grasses of forty per cent., and to the ragweed of sixty per cent. The patient was given a desensitization treatment in 1921, resulting in total relief. The patient reported in June, 1925, that there had been no recurrence of her hay fever.

Case VII.—The next patient had suffered from the socalled rose fever for ten years, and was of such a nervous type that it was difficult to make the necessary cutaneous tests. She was forty-nine years of age, and a native of New Orleans. She was found sensitive to the grass and chenopod pollens, but negative to the ragweeds, which coincide with her attacks of hay fever, which commenced in June and ended about September 1st, when the ragweed pollen begins to become active in New Orleans. Her rule had been to leave New Orleans as soon as her hay fever developed in June for some locality in which she did not suffer, and to return in September when her hay fever season was over.

She was given the desensitizing treatment for the grass and chenopod pollens in 1922. This relieved her almost entirely, and for the first time in ten years she was able to remain in New Orleans without discomfort. In the spring of the following year the cutaneous tests were almost negative, but she was given four extra treatments as a precautionary measure. She has been entirely free of hay fever since that date, in spite of the fact that she remains in New Orleans during her former hay fever season.

Case VIII.—The next patient is a dentist of New Roads, Louisiana, aged thirty-eight, who had suffered for five years from combined spring and fall hay fever. He was referred for treatment June 15, 1920, by Dr. M. O. Becnel. He gave a reaction of forty-five per cent. for the grasses, and seventy per cent. for the ragweeds. The desensitizing treatment was commenced on June 15th, being carried out according to our instructions by his family physician, and on August 9th treatment with the ragweed extract was commenced. The result of this treatment was a great improvement in his condition. In 1921 it was found unnecessary to give the spring desen-

sitizing treatment. The fall treatment, however, was given but was not started until August 15th, so that the patient had one attack of hay fever. The following year the tests gave practically a negative reaction, and it was not found necessary to continue the treatment. In 1925 he reported that he had had no further attacks of hay fever.

These cases are cited to show that the benefit from the desensitizing treatment of hay fever is permanent in a certain number of cases. These cases have been selected to illustrate that this effect may be obtained in cases of long standing (thirty-eight years), in the spring form, the fall form, the combined spring and fall, and in the perennial form of hay fever. These cases are not yet sufficient in number to form any conclusions as to the underlying conditions of a permanent cure, but they undoubtedly form a basis for a further analysis for this purpose.

These cases have been carefully selected so as to avoid other causes than the effects of the treatment in the result. It is well known, for instance, that patients changing their residence are sometimes relieved of their hay fever (2), this being due to the fact that the pollens to which they are sensitive are not found in the new locality, or at least not in sufficient numbers to produce their hay fever reactions. Such cases have been carefully eliminated from this report.

CONCLUSIONS

The desensitizing treatment of hay fever is followed in a certain percentage of cases by permanent cure, and such cases should be carefully analyzed with a view of making such successful results more common.

It is quite possible that patients are given the preventive treatment of hay fever, who are already sufficiently desensitized. Patients should, therefore, be carefully tested before the opening of their hay fever season, not only with a view to outlining the preseasonal treatment, if required, but also, in the case of a negative reaction, to avoid inflicting an unnecessary treatment on the patient.

Eyestrain

OLIVER T. OSBORNE, M.D., M.A., F.A.C.P.
New Haven, Conn.

In this age of overuse of the eyes the condition of eyestrain is very frequent. Beginning with the infant too much use of the eyes is encouraged. There is too much pushing of the baby in a carriage along the streets, with the excitement of the whizzing by of automobiles, to say nothing of the street dust and the carbon monoxide pollution of the air that the child must breathe. Also the young child is too frequently taken automobile riding, with the rapid changes of scenery and the swish of the passing machines.

A little older and the child reaches school where the eyes are the principal portals for knowledge to enter his brain, as evidenced by the whole side, or two sides, of the schoolroom being devoted to windows for extra light. Soon moving pictures are added to his eye work, and a little later increased hours of daylight activity and strong electric lights. Then come parties, automobiling after dark, and more use of the eyes. Next comes higher education of some kind, which must be acquired by use of the eyes; and finally the life work, with the eyes the most important element in the success of such work. Often this work must be done in poorly lighted rooms or in electric overlighted and ill ventilated rooms. Long before this period, frequently as a child, glasses have been acquired for recognized eye defects.

The most frequent cause of eyetire and eyestrain is astigmatism. A person who is given glasses is not sufficiently, often not at all, instructed that, with this eye defect, the glasses must be perfectly adjusted. Consequently, because the lenses become mal adjusted very frequently, no matter what the type of frame, he again suffers eyestrain and therefore decides that "it is not his eyes that are at fault," but that the eyetire or headache or other symptoms are due to his general condition, and a round of other treatment is begun. Also he is not told, or not impressed, by the oculist that his eyes will mold to another degree of astigmatism, and that a reexamination of the eyes and a refitting of glasses will be needed.

Many times the person thinks that anyone with an optician's sign can fit his eyes to glasses, and he suffers according to the amount of the misfit. No blame should apply to the careful oculist who misjudges the correction needed, and the patient should be made to understand, which he does not, that the oculist's science is no more exact than any other branch of medicine. The patient should revisit his oculist until the right glasses are acquired. Also the oculist must insist on the patient returning to him to insure that the glasses are correctly ground and the frames are correctly fitted. Misfitting frames are frequently the cause of what the patient calls "the oculist's failure."

Now, what are the symptoms of eyestrain? Most frequently pain or ache in some part of the head, often accompanied by nausea and loss of appetite, sometimes by vomiting, not infrequently by complete inability to work for some hours. In these cases the diagnosis is easy.

These headache attacks often occur periodically, apparently representing the limit of tire that the eyes can stand. The headaches are brought about by extra hours of work or play, overreading, moving

pictures, theatres, lectures, shopping, moving crowds, watching the waves or viewing mountain scenery, motoring, trolley or train riding, overeating and drinking, constipation, or by any other disturbed bodily function. The headache sufferer gives up one pleasure after another until he or she finally becomes more or less of a misanthrope and is even disgusted with life itself. These eyestrain persons, who all have more or less indigestion, are likely to attribute the disturbance to some food, and will avoid first one article of food and then another without benefit. They commonly believe the trouble is due to constipation and take all kinds of purgatives, and by the sequence of events, *post hoc,* the headache and indigestion cease for that time.

The most misunderstood and neglected cases of eyestrain are those with but little or no headache. These patients may have all kinds of reflex indigestion, or have reflex heart symptoms, or insomnia, lose weight, and are supposed to have a socalled nervous breakdown. This ailing but not seriously sick person very frequently takes nostrums of all kinds. Depending upon his special symptoms he may seek a stomach specialist, a nerve specialist, a heart specialist, or, more frequently, he goes to a pseudopractitioner of some ilk.

If he visits a general practitioner, he will all too often, in this busy age, receive only a cursory examination without much time being devoted to questioning. Questions and answers will develop symptoms and causes of symptoms that the most careful physical examination cannot. Consequently the cause of his trouble is not eradicated and he receives no benefit. If the physician is more thorough, the patient is given a prolonged physical examination with all kinds of tests except an examination of the eyes, which is the test most frequently omitted. He is found to be "neurasthenic" or "neurotic," and a prolonged rest cure, often with sedative drugs, is prescribed.

If he goes to a specialist, he is treated, very frequently, for disturbance of the part of the body in which the physician has specialized without much investigation as to whether or not the symptoms are reflex, and again the patient is not benefited. He continues to spend money and finally becomes despondent, all because the verbal examination was incomplete and an examination of his eyes was not made.

Sometimes these patients suffer for many years before someone (often the patient himself) decides there is an eye defect. He then visits an oculist, obtains glasses that are right, and is cured. Or many times after obtaining glasses on his own initiative, or by the order of his physician, carelessness in the eye refraction or poorly adjusted frames allows of no great improvement; or he may become worse. The eyes are then considered not to be at fault, and he again seeks treatment or gives up his occupation and takes a prolonged rest. Many a youth has lost his whole career by being compelled to give up his studies on account of an undiagnosed eyestrain.

The object of this discussion is to urge that the almost forgotten art of carefully obtaining the personal history of a patient be redeveloped, and that with the very common condition of eyestrain the physician's duty does not end at the oculist's office. The physician in charge of the patient must insist that he know the glasses are right, that the frames are properly adjusted, and that the patient is benefited. Then his duty is to caution that glasses out of adjustment will again cause the same symptoms, or some modified form of the previous symptoms, to develop.

I suggest the following questions for developing the relation of the eyes to the disability:

1. At what age did the headaches first occur?
2. What is the frequency of the attacks of headache, and what is the exact work or play after which they occur?
3. What is the time of day at which the headache develops, especially the relation of the headache to arising in the morning, or to the work or pleasure of the evening before?
4. What is the relation of the headache to close eye work? What is the relation of the headache to an evening at the theatre, or at the movies?
5. Whether or not the person has a growing dislike for reading, sewing, playing cards, shopping, crowds, parades, ball games, trolley riding, train riding, automobiling, theatres and moving pictures.
6. Whether there is a history of car sickness.
7. What are the associated symptoms of the headache, as anorexia (or often the reverse, several hours before the headache a craving for food), or nausea or vomiting?
8. How soon after vomiting does the headache cease, and is the patient soon able to eat a good meal? Such an immediate appetite is of frequent occurrence, and completely rules out acute indigestion or an acute stomach disturbance. The reflex indigestion that is caused by the eyestrain may allow food to remain in the stomach and be vomited hours, even twelve or more, after it has been ingested.
9. Whether or not there are any heart symptoms with the headache? Some eyestrain patients have waves of nausea and sensations of fainting. They often have palpitation, and have, or imagine they have, heart pains.
10. Whether or not there is insomnia? Many patients cannot sleep, lose appetite and weight, and are supposed to suffer from socalled nervous exhaustion, with headaches and insomnia as important symptoms.
11. Whether or not there is history of dizziness? Some patients with eyestrain have queer spells, become dizzy and faint, sway on the street, and walk sidewise. I have had several such cases cured by correct glasses after long previous unsuccessful treatments of all kinds.
12. Bifocal lenses may be entirely inappropriate for the individual, especially when he is out and about. Many a patient cannot drive a car while he is wearing bifocal lenses, or cannot use them for his daily work. Also not infrequently the magnifying lenses of the bifocals are misplaced; they are too high or too low, or too strong for middistance work. The reading lens is frequently utterly inappropriate for the work the person has to do. Two strengths of bifocals must frequently be given if the person is to be comfortable and symptomless. One bifocal should be of the proper strength for reading, and the other, a weaker bifocal, for all ordinary middistance use of the eyes.

Were it worth while illustrative cases could be described, but it is hardly necessary, as every careful practitioner of medicine sees patients with more or less chronic invalidism from headaches. Many a patient will relate the history of periodical headaches all his life until after forty years of age, when they become less and less frequent. This diminished frequency of the headache, or often its entire abeyance, is due to the developing presbyopic stiffening of the lenses, and therefore there is less and less muscle effort to produce an unblurred image. Also, soon presbyopic glasses are required, and at an examination for such the long undiagnosed optic defect is found and corrected. Women think the cessation of recurring headaches at this period of life is due to the menopause. The cause is advancing age, which fact must of course be diplomatically presented to the patient.

Benign Tumors of the Anus and Rectum

CHARLES J. DRUECK, M.D.
Chicago

At the anus and within the pelvic portion of the colon there develops a variety of growths benign and malignant between which the distinction is not always clear. There are many borderline cases and certain tumors which, though not themselves destroying life, may cause much misery through constipation, intestinal obstruction or intussusception, besides ulceration and hemorrhage, and may in time undergo malignant transformation. Of forty-two such cases collected by Quenu and Landel twenty of them ended as true cylindrical carcinoma. These rectal tumors are of different anatomical structure, but each resembles the tissues from which it springs. All rectal tumors incline toward the direction of least resistance, and therefore protrude into the lumen of the bowel. Once the mass extends into the intestinal canal it is dragged upon by the passing fecal current and by the straining incident to defecation until its attachment is drawn out into a slender cord or pedicle and a polyp (or polypus) is formed.

Histologically we find that in benign tumors the cellular elements are fully developed and normally arranged, whereas in malignant tumors the cellular elements are irregularly arranged, are imperfectly developed, and are found growing outside of their normal sites. Further than this we do not know what inherent qualities or characteristics render one neoplasm benign and another malignant. Tumors of the connective tissues are the fibroma, enchondroma, lymph adenoma, lipoma and myxoma. In the muscular structures are the myoma and fibroma which are very benign. In the epithelial structures are the adenoma and papilloma. Irregular growths are also found such as cystomas, fungi, vegetations and excrescences.

Papillomata are cauliflower like, branched and lobulated growths of the epithelium which originate through the baring of the papillary bodies by slight injuries and develop in the presence of the favoring elements heat, moisture and chronic infection. While the influences that give rise to a true papillomata or wart and to a polypus are essentially the same, there is a marked difference in their clinical appearance.

Papillomata occurring on the skin are rough and hard, while those arising from the mucous membrane are very soft and velvety with loose edematous stroma. In both localities, because of constant traumatism, they are frequently inflamed or ulcerated. Because of this difference in clinical appearance papillomata will here be considered under two captions: 1. Those occurring on the skin about the anal or rectal canal. 2. Those occurring within the anal or rectal canal.

PAPILLOMA ABOUT THE ANAL REGION

Perianal warts, papilloma, vegetations, condyloma or verruca, as they are variously called, are perhaps the most commonly met of all anorectal disorders. They are not particularly serious in themselves, but they are sufficiently obstinate things to treat; and it must be borne in mind that warts, especially in the aged, are always potential foci of malignancy. These growths consist of hypertrophy of the papillary layer of the skin and are composed of connective tissue and bloodvessels, together with a covering of epithelial tissue; they are bright red in color, fragile and liable to bleed freely. Little warty tumors develop, which rapidly branch and intermingle with the branches of other warts until they form what seems to be one large tumor, but which, when removed, is seen to be attached to the skin by numerous pedicles (Fig. 1). The moisture and secretions collect between these ramifications and, as a result of maceration and decomposition, these growths throw off a strongly fetid odor. By contact, all of the surrounding tissue becomes inflamed. According to the exuberance of the growth, various fanciful shapes are assumed, these being described as cockscomb, cauliflower and such like. When the connective tissue is abundant and the epithelial covering is thin, the growth is dry and hard (Fig. 2); but when the dermis is thick and the growth is soft, it is moist. The moisture and warmth of the parts favor the development, although an idiosyncrasy exists in stout individuals.

Formerly these growths were considered proof positive of syphilis and sodomy, but, although they may be associated with syphilitic lesions about these parts, they are not necessarily a sign of lues. The discharge of gonorrhea, leucorrhea, hemorrhoids, proctitis or any other lesions may be the cause. The condition itself is not contagious and is not responsive to antisyphilitic treatment.

The vegetations usually develop during early adult life, but are sometimes seen in infants and the aged. Their development in some persons is rapid and slow in others. In advanced life it is thought they result from degenerative changes in the skin. The growths

may consist of a single papilla or it may involve the whole intergluteal area. It may be situated at the anal margin or outward, on the buttock. Often the primary growth begins on one buttock and later affects the opposite cheek. Any kind of irritation would produce the same effect. The symptoms, therefore, vary with the extent of the growths, their locations, and the amount of the secretion.

When the growth is large the patient is aware of a foreign body being present between the nates, and he is annoyed by the foul discharge as well as the fresh abrasions constantly occurring. When the anal margin is involved, defecation causes considerable pain, which may resemble the pain of fissure; there also may ooze out a few drops of blood. Although as a rule these growths develop on the outside skin, they may originate within the rectum.

The differential diagnosis is not difficult, except that it may be mistaken for a mucous patch; its attachment, like that of a shrub, being sufficient to distinguish it. Syphilides have a diffuse infiltrating base and form a broad, flat mass free from any tendency to pedunculation. Malignant growths are deep seated on an indurated base and tend to invade the deeper structures.

Treatment.—Scrupulous cleanliness and the application twice each day of an astringent dusting powder are sometimes all that is needed. In most cases, however, the growths should be clipped off with scissors and hot compresses applied to control the bleeding. If the growth recurs the whole surface should be sprayed with fulguration.

PAPILLOMA OR VILLOUS TUMOR ARISING WITHIN THE RECTUM

These tumors resemble the adenoma closely in histological structure and in the pathological course, but differ from that class of growths by being lobulated like a cauliflower with some of the masses ending in a fine lacelike edge (Fig. 3). The whole growth is spongy on manipulation. This tumor arises from the surface of the mucous membrane of the bowel and is attached by a broad base through a short pedicle never more than two inches long. The growth is flat (plaquelike) and spreads over a wide area, and consists of a number of lobes. These lobes, although they are approximated to each other, are not united, but each has its own pedicle. The pedicles are then attached to each other and into a common base. Each lobe ends in a number of villi or papillæ. The whole tumor may attain a large size, red in color and soft and velvety to the touch. Moffat (1) reported one as large as a human head.

Symptoms.—Early in the history of these growths the sufferer notices a free discharge of thick, tenacious, viscid mucus which much resembles the white of an egg. Rectal tenesmus with a frequent and urgent desire to empty the bowel causes the mucus to be involuntarily discharged thus soiling the clothing and staining the garments a light yellow. This mucous discharge has much the same effect that we might expect from a purulent excretion, the patient is debilitated, pallid and loses weight. There is also some loss of blood, but this symptom varies considerably in different individuals. The hemorrhage may occur only occasionally, there may be daily oozing or streaking of the stools, or it may drip after each bowel movement, or a profuse hemorrhage may occur, which exsanguinates the patient and leaves him in syncope. All of this pathological condition causes little pain.

On digital examination the tumors are soft, velvety or mushy and covered with mucus. The examining finger can be worked in between the lobes of the tumor. The attachment is by a broad, flat base, but there is no induration of the surrounding structures, and it is therefore easily distinguished from the malignant cell epithelioma, and so called vegetating epithelioma.

Diagnosis.—Papilloma is to be especially differentiated from adenoma and vegetating carcinoma, which it closely resembles.

The single adenoma is found almost entirely in children, while the papilloma is found in adults and usually in elderly persons. The multiple adenoma with a broad based attachment occurring in adults presents the uncontrollable diarrhea and mucopurulent evacuations instead of the clear, gluey mucous discharge.

Vegetating carcinoma is friable and has a dense induration about its point of attachment.

Case.—H., aged nineteen years. Patient noticed a slight pain on defecation about three months previously and on examination discovered a large protrusion at the anus. This mass had grown larger and more painful until at examination when sitting on a chair it was tender. She had noticed free blood streaking the stools during the past month. Patient was well developed and well nourished. Local examination revealed a mass about the size of an egg on the anterior edge of the anus growing from a small pedicle. It was covered with small papillæ. Nothing was felt on internal digital examination of the rectum. Fig. 4 shows appearance of tumor. A diagnosis of papilloma of the anus was made.

The tumor was excised at its base and the mucosa closed with fine catgut sutures. Recovery was complete in one week.

ADENOMA

Adenoma is the most frequently found benign growth in the bowel and furthermore it is found in the rectum more often than in any other part of the intestine. Adenomas develop from the mucous and submucous coats of the bowel and contain all of the elements found in these layers. Adenomas undergo early degenerative changes and frequently after they have been removed, there recurs at the site a return of the same kind of a growth or a malignant neoplasm.

The majority of rectal polypi belong to this class and rectal adenomas are so often referred to as polypi that many practitioners consider the terms synonymous. Such, however, is not the case. All polypi are not adenomas, neither are all adenomas polypi. Adenomas undergo hyaline, myxomatous or cystic degeneration but do not develop metastasis. They are found in all ages although those occurring in children differ very much macroscopically, microscopically and clinically from those present in adults. Two different types of adenomas exist, the single adenoma with the long pedicle usually found in children, and multiple adenomas, having broad attachments and usually found in adults.

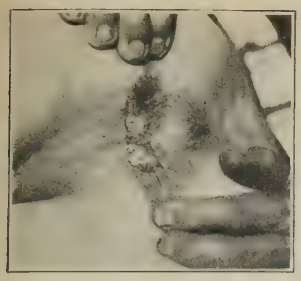

FIG. 1.—Perianal warts. Note the lobulated character of the mass as the buttocks are spread apart.

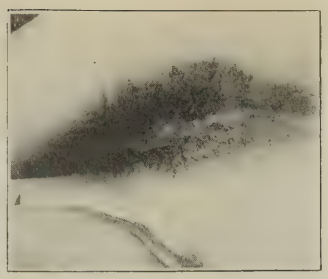

FIG. 2.—Flat dry papilloma at the anus.

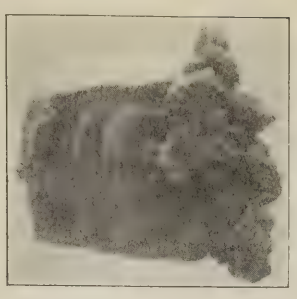

FIG. 3.—Papilloma of the rectum. Specimen in the Pathological Museum of the Northwestern University Medical School.

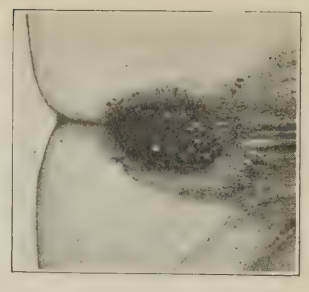

FIG. 4.—Papilloma of the rectum (pedunculated) protruding from the anus.

SINGLE ADENOMA

In children there is usually a single adenoma or at most but three or four, varying in size from that of a cherry to perhaps a hen's egg, each with a slender pedicle which may measure up to six inches in length, depending upon the size and age of the tumor. If the mass has been dragged upon for a long time by the bowel trying to expel it, the pedicle becomes stretched and attenuated. The tumor itself

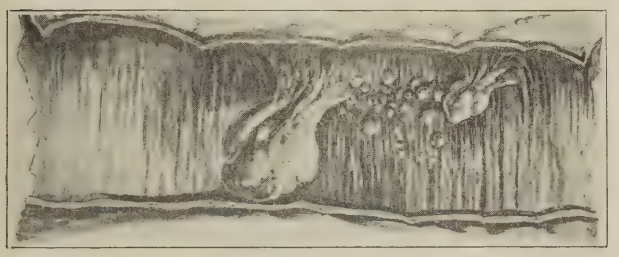

FIG. 6.—Diagrammatic drawing of a case of multiple adenoma within the sigmoid and rectum.

much resembles a red raspberry in appearance. It is ovalshaped, bright red, with a rough surface and consists of a preponderance of connective tissue with a small amount of glandular and epithelial structure. This type of adenoma usually occurs in children under twelve years of age although it is sometimes found in adults (Fig. 5).

The single polypoid shaped tumor occurring in children may be extruded only during acute digestive disturbances accompanied with powerful peristalsis

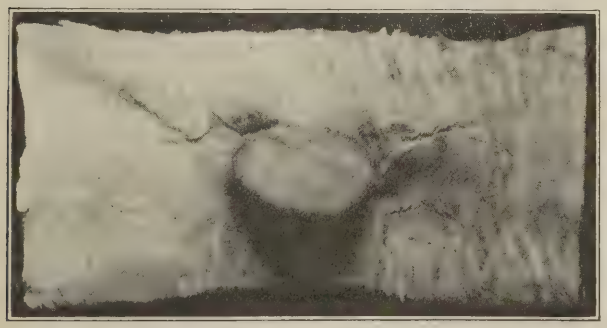

FIG. 5.—Single adenoma of the rectum. Specimen in the pathological Museum of the Northwestern University Medical School.

and tenesmus. At other times when retained within the bowel it may cause obscure digestive disturbance with diarrhea. On examination with the proctoscope the adenoma will often drop into the lumen of the instrument and may be easily removed with a snare rather than clipped off with scissors as by the slow crushing of the snare the intima of the vessels is crushed and there is less danger of hemorrhage resulting. The small stump of the pedicle soon atrophies completely and will therefore need no further attention.

MULTIPLE ADENOMAS

This condition is ordinarily a disease of young

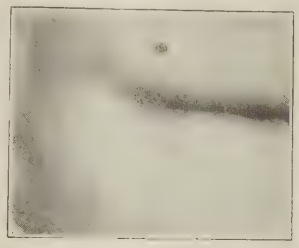

FIG. 8.—External exit of a congenital sinus at the tip of the coccyx.

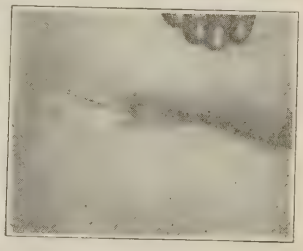

FIG. 9.—Probe passed through the congenital sinus comes out nearer to the anus.

adult life (Quenu and Landel (2) report over fifty per cent. occurring between the ages of twenty and thirty-five years) but it sometimes occurs in children. In the latter two, three or even four separate adenomas may be found with slender pedicles but such a condition is exceptional of the single adenomas. The clinical course of the single adenoma with the long slender pedicle is entirely different from that of the multiple adenoma with the short thick base and moreover the single adenoma of childhood never develops into the multiple adenomas of adult life. The cause of these tumors is not known, although very interesting theories have been advanced. For example, Huber (4) of New York has attempted to show that these tumors are a result of a general systemic lymphatic hypertrophy. The sigmoid and rectum are most frequently affected, although when the tumors are spread over a wide area the whole colon may be affected. There may be several tumors clustered together in one patch of the bowel

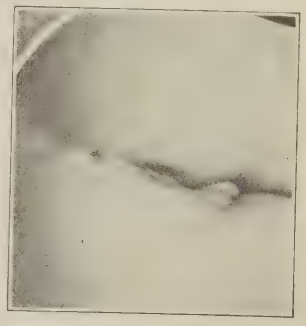

FIG. 7.—Congenital depression or pit at the tip of the coccyx.

and a second collection farther up with an intervening portion of healthy mucous membrane between them that is involved. The sites most frequently affected are those at which the feces are accustomed to be arrested, and because of this fact it is thought that local irritation and infection by the feces is an exciting cause. Fink (4) believes that they begin in the rectum and gradually multiply upward.

With the proctoscope the tumors may be seen, their number, general characteristics and the extent of the bowel involved noted. One of the growths may be excised and examined microscopically but a negative report of one tumor does not determine the character of the others. Three out of four cases of multiple adenomas become malignant sooner or later. Microscopically these tumors are composed of hypertrophied glands and connective tissue covered with cylindrical epithelium.

There is a great variation in the gross appearance of these. In a case seen by the author, an illustration of which is here shown (Fig. 6) a number of tumors were found. The largest one was about the size of a hen's egg, the upper one was as large as a good sized strawberry, and the small ones between these two were the size of green peas. There were also a number of masses which were palpable in the mucous membrane but do not show in the picture. In this case the surface of tumors was smooth but irregular like the surface of a potato. Other observers have reported cases in which the surface of the growth was like a mulberry. Such masses closely resemble villous tumors. The consistency of the adenomas varies much with the proportions in which the connective tissues and the epithelial structures are found. Tuttle (5) believes that the harder the tumor the more likely it is to undergo carcinomatous transformation. The pedicle is composed of mucous membrane, areolar and fibrous tissue and bloodvessels and is usually short and thick; never so long as is that of the single adenoma.

Symptoms.—There are four prominent symptoms in all cases of multiple adenoma, namely, diarrhea, hemorrhage, pain and exhaustion.

The diarrhea which resists all astringent remedies to control is accounted for in part by an associated proctitis or colitis which always is present. The stools are small and contain mucus and also fresh and old blood. If there is much decomposed blood the evacuations are black and disgustingly foul. Occasionally an evacuation may consist wholly of mucus or blood. The pain differs in degrees but is somewhat diagnostic of the location and size of the tumor. Adenoma in the colon, sigmoid or upper part of the rectum occasion tenemus and colic, but those in the ampulla or lower rectum may not cause the pain unless they are so large as to cause obstruction. If that occurs the pain is severe. Prolapse of the rectum may be caused by these growths.

Extrarectal dermoids occur in the tissue of the rectovaginal septum or of the retrorectal space, and also just beneath the skin between the anus and sacrum. Sometimes one breaks through the rectal wall and develops as a pedunculated tumor, the pedicle being attached to the tissues in one of these spaces. These dermoids are similar to those which occur elsewhere in the body. They should be dissected out.

LIPOMA

A lipoma is a tumor composed of adipose tissue. When found in the rectum it develops in the submucous layer. It may form a part of the rectal wall or it may be pedunculated. Because of its origin below the mucosa, if the lipoma is removed its base should be ligated because of the possibility of invagination of the peritoneum into the intestine. Where the tumor forms a part of the rectal wall it should be enucleated through an elliptical incision and the wound sutured.

FIBROMA

Fibroma in the anus and rectum is rare. It originates in the connective tissue of the submucosa and may attain considerable size. It may remain in the rectal wall or it may become a polypus. The socalled fibrous polypus is a fibroma but containing also muscular and glandular tissues. It usually continues through its existence a fibroma but may degenerate into a sarcoma.

Enchondroma is a still rarer form of connective tissue tumor, and is composed of cartilagenous and fibrous tissues. Only a few rectal enchondromas have been reported.

Diagnosis.—Whenever a diarrhea persists longer than a few days a local examination of the rectum and sigmoid should be made, when adenoid if present will be felt and seen. The subjective symptoms tenesmus, colic, diarrhea and hemorrhage indicate somewhat the degree of inflammation and obstruction caused by tumors. Sometimes these growths can be felt in the colon by abdominal palpation. Polypi which have undergone carcinomatous change have a peculiar indurated base, produce a foul discharge due to the breaking down of the tissues, and the ulcerated portion may be seen through the proctoscope. On digital examination several tumors may be felt. These may vary greatly in size, some being as small as a pea and others may perhaps obstruct the lumen of the bowel. Some may have pedicles and others not. The small tumors are soft but the larger ones are firm as a result of inflammatory or carcinomatous change.

A piece of the tumor may be removed and examined by frozen section but the site from which the fragment was removed must be immediately sterilized with the cautery to close the bloodvessels and lymphatics and lessen the danger of invasion by cancer if malignancy exist. Where several tumors exist some may be benign while others are cancerous.

Treatment.—The medicinal treatment of the polypi within the large bowel is very unsatisfactory. Diet has no effect on the diarrhea or discharge, and astringent drugs except huge doses of opium are utterly unable to control the symptoms more than temporarily. Surgery offers the only permanent relief.

The growth must be promptly, carefully and thoroughly removed. Following any less radical treatment they invariably recur. Operation should be performed at the earliest possibility because the tumor increases in size until it may obstruct the canal, also the mucus discharge exhausts the sufferer, and there is always the possibility of malignant transformation. The method of approach will depend on the situation of the growth.

Tumors in the rectal ampulla become pedunculated and are dragged down until they extrude from the anus at each defecation. Such tumors can be removed through the proctoscope with a snare. Sometimes these tumors are sessile instead of pedunculated and must be excised. An elliptical incision should be made through the mucous membrane down to the deeper coats and the edges closed with fine catgut sutures. By so treating the base there is no danger of cutting through an invagination of the peritoneum, should that be present, as might occur when using a snare or a crushing instrument. The wound edges must be carefully approximated with fine catgut to assist prompt repair as otherwise an ulcer may result, and in these epithelioma frequently develops.

Aftertreatment.—The rectum should be cleansed at least twice daily during recovery and the field may be kept scrupulously dry and clean. The patient should be given ten minims of tincture of opium three times each day to confine the bowels. On the fifth day he is given an injection of eight ounces of mineral oil to facilitate defecation and following each evacuation for the next week the lower bowel should be irrigated with normal salt solution. Because of the possibility of malignant recurrences these patients should be kept under observation for at least one year.

Tumors in the sigmoid are difficult to remove through the sigmoidoscope and in such procedure there is always danger of producing perforation of the bowel with resulting septic peritonitis and death. Such neoplasms should be removed by sigmoidotomy, as advised by Mayo (6).

Technic.—The abdomen is opened in the median line suprapubically and a selfretaining speculum adjusted. The patient is placed in the Trendelenburg position, the small bowels packed off and the sigmoid lifted up and opened through the anterior white band at a point opposite the tumor. The neoplasm is exposed and delivered through the incision until sufficient normal mucous membrane is everted to apply double clamps well beneath the base of the tumor. The growth is cut off with the cautery and the mucous membrane wound closed by continuous suture of chromic catgut. The bowel below the site of the growth should be reinforced by a few interrupted silk sutures. The incision in the sigmoid is then closed with continuous catgut and interrupted silk. A long rectal tube is introduced at the anus, passed beyond the operative site, fastened to the anus with a suture and left *in situ* for a few days to prevent the accumulation of flatus.

When the tumors extend above the sigmoid they are not usually localized, but may be found in any part of the colon. In some instances the growths seem to develop as a result of infection and a cure may be effected by complete physiological rest of the entire large bowel for a period of six to twelve months. An ileostomy with a right sided artificial anus should be tried before resorting to colostomy. In the intervening months while the ileostomy is being tried, the rectum and lower sigmoid may be cleared of polypi. Later the bowel may be restored to its function if deemed advisable. Appendicostomy and cecostomy do not serve this purpose because although both permit colonic irrigation and medication, the colon is promptly refilled with and contaminated by fecal contents from the small bowel. Short circuiting by ileosigmoidostomy does not relieve the infection in the pelvic colon. It is often impossible to bring the ileum down to the lowest loop of the sigmoid and, therefore, the disease below the anastomosis will persist. Ileostomy has all of the advantages of a left sided colotomy without its disadvantages. Ileostomy permits drainage of the small bowel and physiological rest with irrigation of the colon. The contents of the small bowels possesses only a slight odor as compared to the constant foul stench of a leftsided artificial anus. There is also very little irritation of the skin if it is properly cared for. Each day the skin is carefully washed with warm water and good soap (castile), then dried and bathed with alcohol; being careful not to let any of the alcohol reach the mucous membrane of the wound. A modified Lassar's paste is used as a coating. Instead of using vaseline for a base as in the regular Lassar's paste I use paraffin. This sets to a firm wax when cold and must be heated each time it is used. When the skin about the artificial anus is well dried the heated paste is spread smoothly over the skin. It soon sets and makes a perfect protection.

The following is the technic of Brown (7): The abdomen is opened in the right rectus line sufficient for exploration. The cecum is sought and the colon carefully examined its entire length. All pericolic adhesions are severed and the appendix removed. The ileum is cut between two clamps close to the ileocecal valve. The distal ileum is closed. A lateral opening is made in the cecum, a large catheter inserted, and the opening closed tightly about the catheter with a purse string suture. A second purse string suture of a No. 1 chromic catgut is placed a quarter inch further out, and three long fixation sutures inserted beneath it. A stab wound is made at McBurney's point through which a forceps is inserted and the catheter and fixation sutures are pulled through the stab wound. The peritoneal surfaces of the cecum surrounding the catheter are scarified and drawn up snugly against the abdominal wall and fixed in the stab wound. A stiff rubber drainage tube is next inserted into the proximal ileum and fastened with a double purse string suture. The ileum is brought out of the lower angle of the rectus incision. The parietal peritoneum is well approximated to the ileum and the abdomen closed.

Later the continuity of the large bowel may be restored if the patient's health warrants and the colonic mucosa has returned to normal, but such a procedure must not be considered too early. Excision of the whole diseased portion may also be thought of. Lilenthal (8) removed the whole colon in such a case with a very satisfactory result. That, of course, is desperate surgery, but is warranted in view of the danger of malignancy.

MYOMA

Myomas are tumors composed wholly of muscular tissue or combined with fibrous tissues and arise from the muscular coat of the bowel. They consist of smooth or nonstriped muscle and fibrous tissue and sometimes contain typical gland islands scattered throughout in which case the growth is called an adenomyoma.

(To be concluded.)

Acidosis, Diabetic Coma and Insulin

JULIUS FERBER, M.D.
New York

Acidosis, the term first used by Naunyn, must not be taken to mean an acid reaction of the blood or tissues. As was pointed out by Henderson, the reaction of the blood and tissue fluids is very constant and under no known condition during the life of the organism does the blood show an acid reaction. An acid reaction of the blood is incompatible with life.

What is acidosis? I shall try to describe the true conception of acidosis from the biochemical facts as they are taught in chemistry and physiology.

When different amounts of acids or alkali are added to water, the range of variation in the H ion is very extensive, whereas in blood the range is very limited, not extending beyond pH7 and pH7.52. In other words, blood can withstand the addition of considerable amounts of acids or alkali without much change in reaction.

This remarkable constancy of the blood reaction is due to certain substances in the blood, chiefly sodium bicarbonate and disodium hydrogen phosphate. These substances are known as buffer substances, meaning that they serve to damp down the effect on the H ion concentration which addition of acids or alkali would otherwise have. A better expression has been suggested by Bayliss, namely, tampon action, since the substances actually soak up much of the added H or OH ions.

Under normal conditions the amount of sodium bicarbonate, the chief buffer substance, is very constant, amounting to fifty to sixty-five volumes per cent. CO_2, and bears a definite ratio to the amount of carbonic acid. The carbonic acid is produced in large amounts during the process of metabolism. This ratio has been estimated as H_2CO_3: $NaHCO_3$= 1:20. The equilibrium between acid and base gives the blood its almost neutral reaction which is indispensable to the life of the organism. This ratio may be increased by the production within the organism of some fixed acid, such as oxybutyric and diacetic acids in the case of diabetes. The acids will combine with the sodium bicarbonate and liberate free carbonic acid. A rise in the H ion concentration under these circumstances is prevented by the remarkable sensitiveness of the respiratory centre to slight increases in the H ion concentration. The centre responds immediately with increased activity manifested by more rapid and deeper respiration and an increased elimination of the very diffusible carbon dioxide through the lungs. The elimination does not stop when the old level of carbonic acid concentration is reached, but proceeds until the original ratio between carbonic acid and sodium bicarbonate is established, and the reaction of the blood restored. If it stopped at the previous CO_2 concentration, the ratio would be too high because there is now less sodium bicarbonate.

Now, although the reaction of the blood has been maintained, there has been a loss of sodium bicarbonate and thus a diminished power to neutralize additional increments of acids into the blood. The diminution of the alkali reserve of the blood is the Van Slyke criterion for determining a condition of acidosis. This may be designated as the limited or specific definition of acidosis. This definition does not embrace all conditions that may raise the ratio between carbonic acid and sodium bicarbonate without decomposing any of the sodium bicarbonate such, for example, as occurs when an excess of carbonic acid is present in the plasma in cases of asphyxia. A more comprehensive definition is that of Henderson: "Any modification of the normal equilibrium between acids and bases within the organism whereby the power to neutralize acid is diminished, is to be regarded as a condition of acidosis."

The plasma itself contains much less phosphate than bicarbonate, but tissues contain a considerable amount of this substance which becomes available when necessary. Blood proteins are important buffer substances. According to circumstances, proteins may act either as acids or as alkali. They are therefore called amphoteric.

Under abnormal conditions, when an excess of acid is added to the blood plasma, they are first neutralized by $NaHCO_3$ and protein. When this is not enough the buffer substances present in the corpuscles may be used. This is accomplished by the transference of K and Na from corpuscle to plasma and by that of HCl from the plasma into corpuscle, thereby releasing base Na in the plasma which as NaCl reacts with H_2CO_3 giving $NaHCO_3$ plus HCl. The HCl on entering the corpuscle reacts with Na_2HPO_4 to form NaH_2PO_4 plus NaCl. The transference of acid through the membrane of the corpuscle indicates that the same process takes place in all other cells of the body.

Another very important means of defense of the body against acidosis is the elimination of N in the form of ammonia instead of urea. The importance of this mode of defense becomes evident when one realizes that one gram of ammonia can neutralize five times as much oxybutyric acid as one gram of $NaHCO_3$. In case of emergency where large amounts of acids are added to the blood the organism can fall back upon the calcium and magnesium of the bones. Gerhard and Schlesinger were the first to point out that in cases of severe acidosis the path of excretion of calcium and magnesium is changed from the bowels to the kidneys carrying with them oxybutyric and diacetic acids. Joslin found in one of his cases during coma, 0.55 gm. of these alkali in the urine, but only 0.15 gm. in the feces, whereas normally forty per cent. of magnesium is excreted in the feces.

We have described above how in case fixed acids are added to the plasma it combines with $NaHCO_3$ liberating CO_2 in the process. In order to prevent a rise of the H ion concentration this CO_2 is eliminated by the lungs as a result of hyperpnea. This hyperpnea is brought about by the sensitiveness of the respiratory centre to any increase in the acidity of its surrounding. The second important pathway for the removal of acid bodies are the kidneys. The

kidneys have a remarkable power of secreting an acid urine from a neutral plasma. If the kidneys excreted the neutral buffer substances after they have combined with the acids the body would soon be demineralized. Each molecule of acid would deprive the body of one molecule of base, the alkali reserve would soon be exhausted and the organism would succumb to acidosis. This is prevented by the power the kidneys have to excrete acid salts leaving behind part of the base with which they have combined. Henderson and Palmer found that in normal subjects it takes between two hundred and eight hundred c. c. tenth normal alkali to titrate the acid urine back to the blood reaction. In other words the kidneys eliminate from two hundred to eight hundred c. c. tenth normal acid in twenty-four hours.

A third pathway for the removal of acid bodies is through the intestinal canal. Some of the phosphoric acid produced in the body is excreted by the bowel.

CLASSIFICATION ACCORDING TO ORIGIN

From this brief review of the biochemical processes which are known to operate in acidosis, it becomes evident that acidosis can be classified, according to origin, as follows:

1. Acidosis due to external causes, such as asphyxia and the inhalation of carbonic acid gas.

2. Acidosis due to changes in the lung tissue whereby the free diffusion of carbonic acid is interfered with.

3. Metabolic disturbances. To this class belong the most important clinical conditions which are associated with acidosis. Chief among these are the severe cases of diabetes. The direct cause of the acidosis in these cases is the production of abnormal amounts of acids, mainly oxybutyric and acetoacetic, as a result of incomplete fat metabolism. The faulty fat metabolism is associated with a deficient carbohydrate utilization. The deficient carbohydrate metabolism may be due to a scarcity of available carbohydrates, such as is found in starvation, or it may be due to an inability of tissues to utilize carbohydrates, which is the case in diabetes mellitus. To this class belong also the cases of acidosis found in severe cachexias, such as carcinoma of the stomach and esophagus, cases of persistent vomiting of pregnancy, infantile diarrhea and vomiting, cyclical vomiting of children, and all conditions in which there is actual or virtual starvation with a complete lack or an insufficient supply of carbohydrates.

4. Renal disturbances. In cases of nephritis there may be an inability on the part of the kidneys to excrete the normal amount of H ions produced in the body. These accumulate in the blood and are neutralized by the buffer substances. The result is a diminution of the alkali reserve which gives us the clinical picture of acidosis.

5. Disturbances of the circulatory system and heart failure cause a deficient and slow blood flow with the result that the carbonic acid produced in the body is not removed as rapidly as in the normal individual. The H ions accumulate in the blood and cause a disturbance in the acid base equilibrium.

6. Toxic acidosis. This is chiefly due to inhalation of chloroform and ether. Almost all patients who have been under a general anesthetic for any length of time develop acidosis.

SIGNS AND SYMPTOMS OF ACIDOSIS

Increased pulmonary ventilation is one of the main safeguards of the body against acidosis; hyperpnea and dyspnea are therefore one of its chief symptoms. If the acid base equilibrium be sufficiently disturbed to produce a pronounced hyperpnea, dyspnea will be felt, while physical effort will accentuate it. Dyspnea due to such causes is to be found in diabetes mellitus and in cases of failure of the renal function. The labored breathing in these cases is not accompanied by cyanosis. It differs from the dyspnea in heart failure which is associated with cyanosis. Apathy, restlessness, loss of appetite, nausea and vomiting are the signs of an advancing coma and are due to the toxic effect of the acid bodies on the system and to dehydration.

As a result of the increased pulmonary ventilation and the washing out of the CO_2 liberated by the fixed acids, the CO_2 tension of the blood and therefore of the alveolar air is decreased. We have then an excellent index of acidosis by determining the CO_2 tension of the alveolar air. For this purpose the Frederica method is the most useful for clinical work. By this method one can estimate the carbon dioxide tension in a short time by a technic which can be easily learned by a physician or nurse in a few minutes.

Normally the carbon dioxide tension of the alveolar air varies between 36 and 45 mm. mercury. A tension below 25 mm. indicates a marked acidosis; a tension between 30 and 25 mm. indicates a mild acidosis.

Once the fixed acids are neutralized by the buffers of the blood they are excreted as acids in the urine. Here they can be easily tested for by the familiar tests of Gerhard and Legal. It has been pointed out by Folin that acetone forms only an insignificant part of the total acidosis and that Legal's test for acetone is really a very delicate test for both diacetic acid and acetone.

In the plasma the diminished alkali reserve can be estimated by the Van Slyke method, whereby the carbon dioxide combining capacity of the blood can be determined. The normal combining power of the blood for CO_2 varies between fifty-five and seventy-five volumes per cent. Figures lower than fifty per cent. in adults indicate acidosis. The normal figure for infants is much lower than for adults. Any figure at or above forty per cent. is not to be considered abnormal.

COMPLICATIONS OF ACIDOSIS

The most serious complication of acidosis is coma. The best known example is diabetic coma. As soon as the acid production exceeds the protective limit of the buffer substances acid intoxication appears, and the patient sinks into a coma. The coma may appear suddenly and be accompanied by deep, noisy respirations without stridor. The pupils are dilated, the pulse is small, and the temperature is usually below normal. On the other hand, the coma may be preceded by headache and sensations resembling intoxication with alcohol. Other prodromal symptoms are vertigo, unrest, delirium and fear, until finally loss of consciousness and collapse become prominent. Once the patient is in coma, death sometimes occurs very rapidly, at other times only several days after the onset of coma. The chances for recovery are best

in diabetic coma, where with the combined use of insulin and proper dietetic and hygienic measures many a patient has been saved.

DIFFERENTIAL DIAGNOSIS

Coma may be due to a large number of causes. One must remember, however, when called upon to see a patient in coma, that there may be more than one cause for the condition and that it may not be at all easy to arrive at the proper diagnosis. Sometimes, in the prodromal stage of diabetic coma, there may be a large amount of casts in the urine which may give rise to uremic as well as to toxemic coma. Broadly speaking, one may divide the cases of coma, for the purpose of differential diagnosis, into those cases where the coma develops in the course of a known malady which may have existed for years, and into those cases where coma is the first sign of disease. In the first class belong the diseases due to metabolic disturbances. However, there are cases of diabetes and nephritis where the symptoms have passed unrecognized until coma announces the disease.

A careful history, if obtainable, is the first step in the diagnosis. Has the patient been suffering from any disease prior to the onset of the coma? The nature of the symptoms. Is there any evidence that the coma may be the acute effect of drugs, such as alcohol, opium, chloral or veronal, or of carbon monoxide poisoning? The general appearance of the patient, pallor, cyanosis or the bright cherry red color found in carbon monoxide poisoning. Evidence of paralysis or head injury. Are there evidences of edema or ascites? Pupils, are they dilated, pin point, etc.? Finally come the examinations of the urine, blood and respiration.

CAUSE OF DIABETIC COMA

As oxybutyric acid, acetoacetic acid and acetone are excreted in the urine all three substances have been considered to be the cause of coma. But acetone is only a decomposition product of acetoacetic acid so it can hardly be responsible for coma. The work of Neubauer, Kennaway and Hurtley would seem to establish the view that acetoacetic acid, and not oxybutyric, is responsible for coma. It has also been shown by Trevan, that when acetoacetate is injected into a cat in neutral solution hyperpnea, coma and a fall in blood pressure take place. These results follow, although the reaction of the blood is not changed. Trevan and Hurtley have therefore suggested that the acetoacetic acid did not produce any symptoms in virtue of its H ion group, but because of the enolic group $\overset{COH}{CH}$. Oxybutyric acid has no enolic group and therefore does not produce this effect.

This work explains why injections of $NaHCO_3$ is unsatisfactory in the treatment of coma. $NaHCO_3$ will raise the alkali reserve of the blood and prevent demineralization of the body, but it can not influence the poisonous action of the acetoacetic acid. This was confirmed by an observation of Allen who raised the alkali reserve of the plasma to and above normal without influencing the fatal outcome of the coma.

TREATMENT

I shall confine my few remarks to the treatment of diabetic acidosis and coma. An acidosis in the course of diabetes means that the carbohydrate utilization has fallen below the minimum requirements of the body. The indication for treatment is to raise, by all known means, the glucose metabolism. Diet, today just as much as before the advent of insulin, is the most efficient means of controlling diabetes. One must not fall into the mistake of allowing the patient to eat all he wants just because he gets insulin. Insulin is a very useful drug and some diabetics can not live without it, but remember that insulin, administered without a proper understanding of what it can do, may do harm.

Alkalies, though not used at present in the excessive doses that we used to prescribe a number of years ago, are nevertheless useful, 1, to raise the alkali reserve and prevent demineralization of the system, and 2, to enable the neutralized acids to be excreted more freely.

Alcohol in small doses well diluted is indicated in this condition.

Plenty of rest and general hygienic precautions are important prophylactic measures against coma. The patient should avoid chilling, exposure and overwork.

INSULIN

The advent of insulin has changed the whole outlook of the diabetic. From all indications so far, it would seem that once a patient has become a well established diabetic, he will probably retain a diabetic tendency for the rest of his life even with the use of insulin.

The methods of using insulin and the aims to be achieved by its use differ among the various workers in metabolism. Some use insulin to the point of getting a normal fasting blood sugar, while others try to prevent glycosuria but do not think it advisable to lower the blood sugar to normal. Still others, like Boothby and Woodyatt, do not object to the presence of both glycosuria and hyperglycemia.

In case of the average diabetic who has to work for a living, it is a question whether they can be subjected to that lengthy and painstaking supervision necessary in order to obtain a normal fasting blood sugar. Moreover, once this is obtained, the increase in diet which must follow eventually will in most cases raise the blood sugar above normal. However, it certainly should be the aim of the physician to clear the urine of all sugar. This I should consider the minimum requirement of any efficient method of treatment with or without insulin.

As a general rule, acidosis and coma are the clinical indications for the use of insulin. The fact that a diabetic passes sugar in the urine is no indication for its use. How often do we get patients who pass four to six ounces of sugar in twenty-four hours' urine, but when put on a proper diet will return in a few days sugar free. These patients surely have a fairly large carbohydrate tolerance and when they adjust their diet to the basic metabolism requirements will remain sugar free. Surely such a patient is not a case for insulin treatment. Insulin is to be given to diabetics who, after a careful tolerance test, show a carbohydrate metabolism below the requirements of the individual. As a general rule, but not without exceptions, when the carbohydrate metabolism of a patient falls below ten per cent. of the total energy requirements this patient is in danger of developing acidosis and insulin is indicated. The insulin should be continued until such time as the carbohydrate tol-

erance has been raised to above fifteen per cent. of the total energy requirement.

After what has been mentioned regarding the indications for insulin, it is not at all surprising to find that the most dramatic results of insulin are in cases of acidosis and coma. Patients who have been deeply unconscious have been brought back to consciousness in a few hours with the use of insulin.

When insulin is given to a patient in coma there is great danger of producing a hypoglycemia with no signs or symptoms to guide us. Repeated blood examinations are the best index of the blood sugar level. When this is not feasible, the patient must be catheterized every hour and the urine examined for sugar. When the urine becomes free of sugar, one must consider carefully the time and dose of the next insulin injection. Under these circumstances it is probably best to give a definite amount of glucose with each unit of insulin. One to one and a half gm. glucose for each unit of insulin given by mouth, subcutaneously or intravenously as the case may be, is the best precaution against hypoglycemia.

It is usually stated that one unit of insulin can bring about the oxidation of one gram of glucose. So that at the beginning it is safe to give as many units of insulin per diem as there are grams of sugar in the twenty-four hours' urine passed. It is best to give insulin in three portions daily half hour after breakfast, lunch and dinner. As the sugar disappears from the urine, decrease the insulin gradually or increase the diet if the patient is losing more weight than is desirable.

Hypoglycemia may result from too large a dose of insulin or from the fact that the patient omits a meal. Vomiting, diarrhea, overwork, enteritis with lack of food absorption or an increase in the natural tolerance for carbohydrates, may cause hypoglycemia.

A patient who is given insulin should be warned against the early symptoms of hypoglycemia, such as sudden hunger, weakness, tremor, chilly sensation, dizziness, fatigue, nervousness and flushing. More severe symptoms are sweating, marked anxiety, delirium, unconsciousness, convulsions and collapse.

In the mild cases the juice of an orange, a lump of sugar or a tablespoon of corn syrup is enough to give complete relief of symptoms. In severe cases where the patient is unconscious, hypodermic injections of adrenalin and intravenous injections of glucose are necessary.

Anomaly of Peritoneum*

HARDIE LYNCH, M.D.
Los Angeles

The man in which this condition was found was forty-five years old. The diagnosis of chronic appendicitis, peptic ulcer, and tentatively, chronic cholecystitis was made. He also had a ventral hernia and bilateral inguinal hernia.

He was operated upon July 15, 1925, by Dr. James A. Mattison. A definitely chronically inflamed and adherent appendix and gallbladder were found and removed, also a duodenal ulcer which was excised, inverted and a posterior gastroenterostomy performed. The herniæ were repaired. He made an uneventful recovery.

The completed stomach operation presented the picture of a posterior gastroenterostomy which bore absolutely no relation to the transverse colon and the transverse mesocolon, the reason for this report. A brief description of the development of this part of the peritoneum will show how the anomaly occurs.

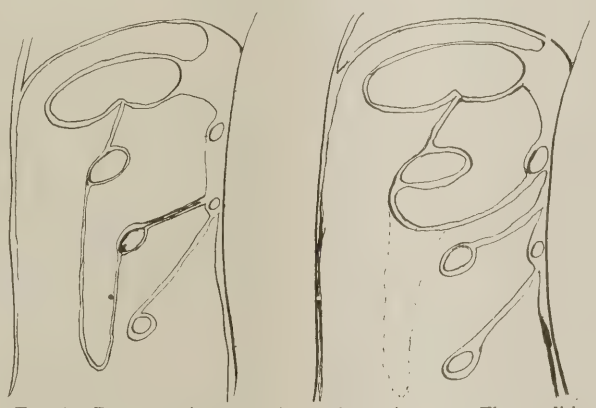

Fig. 1.—Demonstrating anomaly of the peritoneum. The condition found in the case reported is shown in the figure at the right. (*Gray's Anatomy*, p. 1252, Figs. 974 and 975.)

In fetal life the omental bursa, which at first reaches only as far as the greater curvature of the stomach, grows downwards as a double layered pouchlike fold, the interior layer being derived from the right leaf of the primitive mesogastrium, its exterior layer from the left leaf. This omental sac or greater omentum extends downward as an apronlike fold in front of the transverse colon and small intestine.

The anterior layer of the transverse mesocolon is at first quite distinct from the posterior layer of the omental bursa, but ultimately the two blend, and hence the greater omentum appears as if attached to the transverse colon. During a considerable part of fetal life, the transverse colon is suspended from the posterior abdominal wall by a mesentery of its own. This condition sometimes persists throughout adult life (as it did in this case), but normally adhesion occurs between the mesentery of the transverse colon and posterior lamella of the greater omentum.

The persistence of the fetal type in this case explains then why it was not necessary to perforate the transverse mesocolon in order to reach the posterior wall of the stomach. It was the posterior lamella of the greater omentum which was opened, the transverse mesocolon, of course, taking no part in the boundary of the lesser peritoneal sac.

Problems in Venereal Prophylaxis

ETTIE A. ROUT

London

After spending some three or four months in Chicago, studying and lecturing, there are a few observations I desire to record, in the hope of contributing to a better understanding of the problems involved.

COMPULSORY NOTIFICATION, EXAMINATION AND TREATMENT

My opinion is that legislation providing for these matters is right and necessary, in the interests of the health of the individual and of society. The fact that not all cases are reported by medical practitioners and not all cases are under treatment does not nullify the benefits of such legislation, though such nonobservance may, at times, lessen the benefits. The mere existence of the legal machinery is often sufficient to ensure that diseased persons do voluntarily seek treatment and voluntarily refrain from endangering the health of others. Similarly the prohibiting of treatment by unqualified persons and prohibiting the sale of quack remedies undoubtedly protects the public from a large amount of these evils.

In operation, however, we cannot group together cases of syphilis and cases of gonorrhea, so far as this kind of legislation and its benefits are concerned. We know how to render syphilitics noninfectious with almost absolute certainty by a comparatively short course of treatment, and the general public is frightened of syphilis and usually willing to consent to such treatment. The course of treatment being comparatively short, the followup system applied to absentees is fairly efficient. There does not seem to me a doubt that the arrest and isolation and treatment of syphilitic prostitutes known to be spreading disease are measures of great social value; and I am sure they can be operated with kindness and efficiency and without imposing undue hardship or humiliation on women who are catering to the sexual needs of the community.

But the gonorrhea cases furnish a more difficult problem—especially in women. The public is not afraid of gonorrhea; men and particularly women postpone and neglect securing adequate treatment; diagnosis and treatment are in many cases more or less uncertain; the standard of socalled cure is hard to define; and in fact it is doubtful if women really badly infected can be cured at all in the light of our present knowledge. In any case the course of treatment is so long—months and sometimes years being necessary—that patients become wearied and disheartened; and it is difficult, if not impossible, to devise a followup system which will insure their attendance till discharged by the medical officer.

STATISTICS

Nearly all the statistics I was shown in Chicago and New York were officially admitted to be incomplete and misleading. In a clear and straightforward report issued by Dr. Louis I. Harris, Director, Bureau of Preventable Diseases, Department of Health, of New York, under date December, 1923, the director repeatedly deplores this fact.

"The total number of reported cases for the year was, of course, small in relation to the actual number which occurred in the city during the year," he says. "What can the department do to obtain more correct statistical data in regard to syphilis in the city? The laboratory has apparently reached very nearly the limit of its usefulness as a source of information. . . . It is in the case of gonorrhea that both institutions and private physicians are particularly remiss in failing to report cases under their care."

"The total number of syphilis cases reported by institutions during the year is 4,060. Evidently a small fraction of the total cases of disease found in syphilitic persons treated by our hospitals during the year," says the director; and the total number reported by physicians for the year was 2,012. And as to gonorrhea, the total number reported for the year by institutions in all boroughs was 2,384, and by physicians 1,194. That is to say, the official statistics of new cases show up as follows for the year 1923 for the city of New York, with a population of over seven million persons: syphilis, 6,072; gonorrhea, 3,578.

And yet we know there are at least four times as many cases of gonorrhea as of syphilis. The principal value of these statistics, therefore, is to prove that there is wholesale concealment and wholesale neglect; and no statistical information should be issued officially unless accompanied by official warnings, such as those given by Dr. Louis I. Harris, that the magnitude and significance of the venereal disease problem are much greater than can be exposed by official statistics.

CHICAGO VS. NEW YORK

Public opinion, and consequently official action, is more advanced in Chicago than in New York; but the readiness of the departments of health of both cities to work in generous rivalry and mutual helpfulness is necessarily stimulating to thought and action. Chicago struck me as the more energetic; New York as the more humane; thus their cooperation should ensure efficiency as well as kindness, and the sharing of knowledge and experience will make both departments richer and more fertile.

REGULATION OF PROSTITUTION

There is a delusion in both cities that regulation has been abolished. Really, more or less inefficient regulation has been substituted for more or less efficient regulation. When prostitutes are subject to arrest, hospitalization, and release if and when noninfectious, a yellow ticket system is practically operative: the only thing missing is—the yellow ticket. It was surprising to hear apparently intelligent Americans allege with one breath that regulation was useless because prostitutes could not be guaranteed as noninfectious and with the next breath allege that nonregulation was valuable because surreptiously it did that very thing. For the efficient regulation of prostitution, what we obviously need is

French law, English administration, American sanitation, and German science. The French cannot carry out their own laws efficiently because of careless and insanitary habits; the English cannot make laws about prostitution, because they are without mental courage; the Americans cannot administer such laws because of their police methods; and the Germans are necessary because their disinfectants and prophylactics are the most suitable for the purposes. Vice can be made safe as soon as these factors are combined in practical operation.

CRIMINAL OFFENCES

I was informed in New York that there is actually an amendment to the code of criminal procedure in relation to the definition of vagrant, by means of which any person who sells or offers to sell and any person who buys or offers to buy sexual intercourse can be arrested as a vagrant—this act to take effect September 1, 1924. But sexual intercourse, regular or irregular, legal or illegal, mercenary or nonmercenary, is not and cannot be made a crime, and most people still decline to regard it as even antisocial except in so far as it spreads disease or sows illegitimacy. Efforts to make criminal what is merely immoral result in placing power in the hands of the police which it is subversive to the welfare of all sections of society for them to hold. The present proceedings in the morals courts prove this. For example, I sat beside the judge in Chicago morals court and heard this case: A foreign commercial traveler was charged with having contact with a prostitute in a hotel. He suffered loss of business and delay; then his case was adjourned; at the adjournment his consul appeared for him with sworn testimony to the effect that the traveler had gone to the hotel on arriving late at night, had been offered the only available bedroom, went up to see it, deposited his belongings there, left the door ajar, and came down to the hotel manager's office to complete engagement and pay for the room. On returning upstairs he encountered the police, who accused him of immorality with a prostitute in the next room. The traveler denied the charge; so did the woman; and the hotel manager's evidence and register corroborated the traveler's statements. The judge dismissed the case and reprimanded the police. This kind of thing does not establish morality: it merely reinforces blackmail. Immorality cannot be abolished by law—only replaced by virtue; and virtue is based on freedom, health and cleanliness—not on fear, disease and filth.

FREEDOM OF CONDUCT

It should be frankly admitted that there is a vast amount of irregular sexual intercourse in all sections of society. In so far as this is casual, it is highly dangerous; in so far as it is loveless, it is highly antisocial. But the large measure of economic independence American women enjoy renders certain the increase of romantic friendships. A thousand years ago the peoples of Europe fought and won the battle for freedom of movement: the feudal system was abolished and slavery of body became a thing of the past. Try to fancy a modern employer claiming the "right of the first night" with the bride of one of his workmen, and we realize immediately how far we have traveled towards liberty, equality and fraternity. Five hundred years ago we fought and won freedom of thought. Religious persecution gradually ceased; science superseded sacerdotalism; the spread of knowledge began, and slavery of mind received its mortal wound. Today we are fighting and winning the battle for freedom of conduct. Men and women alike are claiming their bodies as their own, to do what they like with, so long as no harm is inflicted on others. It is the welfare of the human group—society—that now appeals to our conscience rather than the interests of the prehuman unit—the brute family of father, mother and cubs. Then we see that it is not continence—still less abstinence—that will stamp out prostitution but rather the wider and freer development of romantic and passionate love relationship. Prostitutes are inconstant and promiscuous; lovers are constant and highly selective; and it is promiscuity which spreads disease, and faithfulness which limits it. We cannot regulate irregular intercourse by having none of it; but we can easily direct it along its natural channels—unions between those who love one another. Chastity is sexual intercourse between those who love one another; unchastity is sexual intercourse between those who do not love one another; no sexual intercourse at all is neither chastity nor unchastity; it has no significance at all.

SOCIAL ENVIRONMENT

The general social environment in Chicago and New York lends itself to the development of friendships between men and women. The well warmed closed in comfortably upholstered motor car which almost everybody possesses renders it possible to set up a private room at any time in any place; and high wages and the keen demand for labor enable every member of the family to live independently if they wish. Gigantic buildings are being erected as bachelor apartments—simply a bedroom, bathroom and perhaps a kitchenette—and these are rented by single men and single women. Road houses are all over the landscape—dance and supper rooms with sleeping accommodation and ample parking for cars. The conglomeration of different nationalities and even different races tends to broaden ethical standards in some respects; and the devotion of the newspapers to the personal affairs of other people is relished by the great mass of the public, and tends to set up a moral common denominator for all classes of society. Nominally hotels do not let bedrooms to men and girls: actually there is no difficulty in engaging rooms in most hotels; certain hotels cater almost exclusively to this kind of accommodation, carrying on business by means of more or less expensive understandings with the police. The least harmful effect of legislative restrictions is to increase the unearned increment on the policeman's salary. The most harmful is to separate immoral women from their toilet arrangements and thus cultivate microbes on the unwashed genitalia of men and women.

MEDICAL PREVENTION

I was informed authoritatively both in Chicago and New York that the hospital and clinic provision for treating venereal disease cases was inadequate. Every effort should be made to increase this to meet the needs of the hour, first for the sake of cleaning up cases of disease, and second for the sake of in-

forming the public as to the magnitude of the evil. Once the public thoroughly apprehends how fearful the venereal disease problem is, they will soon convince themselves that it is quite as moral to prevent disease as to cure it—and much cheaper. Undoubtedly every case cured or rendered noninfectious is an important factor in prevention; but no infectious or contagious diseases have been brought under control by picking up developed cases as they arose and curing them; and with many cases of venereal disease cure is only a relative term. The way to stamp out contagious diseases is to prevent new cases arising at all.

It is fatuous to contend this can be done by lessening contacts. Our sexual contacts have probably been much the same per thousand per annum for the last million years. I have heard American social uplifters argue that venereal disease stands in direct and definite ratio to the number of contacts; therefore the less the number of contacts, the less disease. It is a preposterous fallacy. By means of antisepsis all forms of venereal disease can now be prevented with almost complete certainty, regardless of the risks incurred.

Numerous instances are quoted to show that in certain badly conducted brothels, American soldiers were poisoned with sexual diseases by French prostitutes—each prostitute having contact with from twenty to fifty soldiers a day. This disgusting performance should not have been permitted, but in any case it need not have resulted in disabling the soldiers. If instead of wasting their time counting contacts, the American social uplifters had established prophylactic stations in the brothels, the health of the soldiers would have been saved; and what was the American medical service about? They had no more right to let men go into venereal areas without antiseptics than they had to let them go into gas areas without masks or walk through a shower of shrapnel without a helmet. And when it was known that the men had been in a venereally poisonous area, failure to provide the antidote was tantamount to aiding the enemy by rendering our men unfit to fight. So now, in the midst of the peace which passes all understanding, no section of society has any right to hinder or oppose the spread of what is really life-saving knowledge—antisepsis as applied to any contagious diseases, more especially contagious diseases which are hereditary or congenital, and afflict innocent and guilty alike.

PROPHYLACTICS

It must, however, be admitted that many substances recommended as prophylactics are unsuitable or disagreeable. The meanest man or woman has some appreciation of sexual pleasure, and prophylactics which lessen pleasure will never be popular—therefore will be of little use in preventing disease. For example, calomel ointment is unsuitable internally for women; it causes salivation and irritation. Greasy substances used beforehand are thoroughly disliked, as being messy and uncomfortable, reducing friction and destroying direct contact. I have tried out various kinds of suppositories for years and found all of them unsatisfactory in different ways—usually because of stickiness or greasiness. For nearly two years I have been experimenting with different kinds of effervescing suppositories, and at last have attained success with a tablet which is being sent to Chicago for a prophylactic packet for women. Laboratory tests have shown that these prophylactic tablets will destroy the gonococci by contact in one minute—the weakest dilution of chinosol which kills the gonococci in one minute is one in four thousand; and the tablet gives us approximately one to one thousand to one in two thousand, assuming an average amount of secretions. The tablet is stainless, odorless, tasteless, nonirritating, nongreasy, readily soluble in moisture but unaffected by heat—therefore of great value for tropical countries, where the ordinary cocoa butter suppository is useless. After prolonged experimental research, in which I have been aided by bacteriologists, physicians, government analysts, and manufacturing chemists, and careful trial, I am now satisfied something has been evolved which will be acceptable to ordinary men and women for use before connection, when it will protect both parties; and if used afterwards only, it will help to protect women from infections in the genital passages.

Such a tablet, when properly packed, is readily portable; requires no apparatus; and does not affect sensation. If it could be put on sale as frankly and simply as toothpaste or hairshampoo, fresh infections would certainly be largely reduced; and there is really no natural reason why prophylactics should not be sold as openly as toothbrushes. We have long since ceased to rely on dirt and disease as aids to sanctity: why then do some of us still wish to found sex morality on them?

EDUCATION IN SEX HYGIENE

I interviewed numbers of Americans who favored such education, but in most cases found their ideas hazy and confused, no matter how high their ideals may have been. They really did not know what to say nor where to begin in regard to the teaching of human sexual reproduction, let alone human sexual intercourse. Vaguely there was an agreement that it was desirable to begin with the vegetable kingdom—perhaps begin with asexual reproduction; but nobody saw clearly where the paths in this educational hinterland were leading. Many used the term social hygiene as a cover for doubt and indecision. Doctors thought there would be fewer unhappy marriages if wives would take more interest in marital intercourse: the problem of frigidity in young married women baffled them. Welfare workers seldom had any ethical ideas higher than the doctrine of continence—a mingling of savage self-immolation and barbarous cruelty—and rejoiced that they wished for none. A few doctors wanted still more sex suppression: but the majority were wholeheartedly in favor of sex expression and preparation and training of young men and young women for marriage.

Everybody was in perfect agreement that prophylaxis should certainly be taught to venereally infected persons—men and women—to reduce the chances of reinfection. That proposal I made to the health departments both in Chicago and New York, and it was readily accepted by them, and by conferences of medical practitioners and others. It was also accepted as desirable that lectures on antisepsis

in regard to the venereal diseases should be given to medical students at the colleges and universities. Lectures to the general public were more difficult to arrange, but were not regarded as wholly impracticable. The chief obstacle was the misapprehension that teaching prophylaxis would lead to encouraging immorality; but even some apparently hopelessly unpromising minds have been disabused of this notion during the last two or three years. Those of us who have taught prophylaxis and given out packets by the thousand know perfectly well that it is impossible to give such teaching and distribute such medicaments properly without at the same time enhancing the danger sense of those we instruct. Thus fewer risks are run—not more. Such caution is admittedly a poor substitute for virtue, but it is better than neglect leading to damaged health.

WELFARE WORKERS

The training and experience of welfare workers in Chicago and New York seemed to me quite as inefficient and inadequate as in other English speaking communities; and many of them obviously suffer from fixation of the brain cells. A disastrous development of welfare work is the setting up of subsidized societies and colleges, endowed with subscriptions available only for moral suasion efforts. It is clearly the duty of honest welfare workers to prevent venereal diseases by all the means known to society. No advocate of prophylaxis dreams of underestimating the importance of selfcontrol and constancy as factors in lessening risk: we merely say that chastity is a positive, not a negative, virtue, that society must provide for the normal sexual needs of its members, and that the majority of men always have and always will regard women as indispensable to health and happiness. But it is practical experience of life which teaches this—not argufying about it. Therefore welfare workers should undergo training in the venereal disease clinics—public or private. I attended one private clinic in Chicago five hours a day for several weeks, where the infections were the result of ignorance, innocence, drunkenness, and sex appetite, the majority of the patients being taxidrivers, policemen, industrial workers, shop girls, prostitutes and pimps. Scarcely any of the men and none of the women had an adequate knowledge of prophylaxis, but they were all ready to listen to instruction and most of them anxious to acquire knowledge. One important feature was that the pimp brought in the prostitute he was running to see if she was free from disease, to learn how to keep her clean, and if found to be infected—he arranged and paid for her continuous treatment. Thus the pimp has come to have a social value, as the medium through which medical supervision can be exercised where it is most needed. Women welfare workers are the most inexperienced as to the sex life of fair average collections of men and girls; and they almost entirely fail to realize the atom sorting processes to which humanity responds, whereby some women inevitably become prostitutes, some free lovers, some conventional wives and mothers, some foster parents, some neuter workers, some perverts, and some apparently repeat in their adult life the embryonic race history of their ancestors—from promiscuity to monogamy.

THE FUNDAMENTAL POSITION

The fundamental position is this, and till it is recognized no headway can be made: That the sexual possibilities of mankind are greater than the sexual requirements of permanent love and marriage. Therefore irregular intercourse is inevitable for imperfect humanity, and failure to make this irregular intercourse safe will result in making marriage the most dangerous of all our social institutions.

20 Bedford Street, Strand.

The Prescription of Exercise and Diet*

C. WARD CRAMPTON, M.D.
New York

(*Concluded from page* 614)

Printed form.—The best form of diet prescription is printed, and for this purpose there are several varieties.

The health consultant may have at his disposal printed diet sheets for different diseases and conditions. The Life Extension Institute, which uses this method, has twenty-five different diet forms. These fill the need relatively well. They are so convenient, however, that it is easy to prescribe the diet which most nearly fits the case, and to be satisfied with an approximate instead of an exact prescription. This method has the disadvantages of the Bed of Procrustes.

Prescription by food classes.—An endeavor has been made to place on a single sheet the common articles of food arranged according to the classes in which they fall, with reference to chemical composition, bulk, vitamine contents and appropriateness to different pathological and constitutional conditions. This has worked out well in private practice and in health clinical service. For example, a health client who is constipated, nephritic, fat, with pyrosis and colitis, can be instructed on this one sheet, whereas, if we had separate sheets for each condition, we would be at a loss to know which one to select.

Prescription by menu.—It is a great help to the client, and to the client's wife, to be given a series of menus for breakfast, dinner and supper, which can be used as a guide for the diet. This requires a great deal more preparation of printed material, time and trouble, but it eventually will become one of the standard methods in health prescription.

*Read as part of a symposium on health examinations, presented under the auspices of the Medical Society of the County of New York and the New York Academy of Medicine, February 3, 1925.

Books.—The lay public is acquiring much information on diet, exercise and other practices in life management. There have been prepared books on the subject of diet, written by physicians, which could be used to aid the efficiency of the diet prescription. It will be wise, however, for the physician to become acquainted fully with the contents of the book before adding it to the prescription. *Diet and Health with a Key to the Calories,* written by Lulu Hunt Peters, M.D., can be highly recommended. A similar book on constipation would make a great contribution to the general welfare.

PHYSICAL CONDITIONS UPON WHICH THE PRESCRIPTION IS BASED

In diet prescription we must consider three main elements: 1. The gastrointestinal tract. 2. The entire constitution. 3. The question of allergy.

The gastrointestinal tract.—The high spots in the gastrointestinal tract are the stomach and colon. In the stomach we have to consider two outstanding conditions. The first is atony, a weak stomach with delayed digestion and fermentation. The characteristic accompaniments of this condition are ptosis and asthenia. This condition requires a rapidly digestible diet followed by exercise and constitutional stimulation, with, perhaps, direct therapeutics. The opposite condition, hypertonicity, with contracted, rapidly emptying stomach, with increased hydrochloric acid and tendency to ulceration, will receive its proper dietary treatment according to the well established medical procedure. The colon similarly presents the same outstanding features—hypertonicity, and the opposite atonic static condition, although stasis quickly accompanies spasticity. There is a large field for hygiene and therapeutics combined.

The whole body.—The circulation, nervous system, glands, muscles, skin, and again the gastrointestinal tract, are all affected favorably or unfavorably by what is offered for digestion. Here again, the most prominent factors are the carbohydrate and protein poisons, which must be considered with due regard to deficient or too rapid metabolism. Under this heading should be considered all of the tendencies toward fibrosis, deterioration—which is the term to be preferred to old age—and the ever present but often neglected endocrine background.

Allergy.—In the future, we shall be much more able to trace constitutional conditions, not apparently associated with the digestive tract, to specific protein sensitization. Many a child has been seriously damaged by fond parents who have insisted on his eating oatmeal or other foods to which he is sensitive. We are now getting large numbers of cases of hardening arteries in adolescents and young adults, which, when thoroughly searched, reveal some protein sensitization. It is a question of whether this will not throw a revealing illumination upon the hitherto obscure causes of adult arteritis and hypertension.

SUMMARY

In addition to the ordinary clinical indications for special care in diet, the health consultant must be alert to provide special guides in cases which show a preclinical fibrosis in the circulation, lung or kidneys, in constipation, overweight and in calcium and vitamine deficiency. With all of these factors in mind, the physician must be alert and skillful in actually producing the desired change in the life habits of his client. This is a feat far more difficult to accomplish than mere diagnosis, however difficult that may be.

EXERCISE

Muscular exercise is useful in various fields of medicine. It may be used to aid the actual disease. It is helpful in prevention of illness and in the correction of such preclinical conditions as constipation, early fibrosis, overweight and ptosis. It is particularly valuable in the program of the health physician in the development of a degree of health superior to the ordinary mediocre condition of the man in the street.

Exercise will not be considered from the viewpoint of developing mere superior muscular ability or muscular size. We are not interested in the development of a winning athlete or a clever gymnast. We are concerned in using athletics and sports for the improvement of living, and we permit the faddist who wishes to use his body as a means of gaining prominence and applause, to pursue his course as he sees fit. Large muscles are out of date. We want only such muscular equipment as will support a vigorous life and will provide a sufficient basis for reasonable success in an enjoyable and healthful pastime. The use of exercise in clinical and preclinical medicine depends upon its values. The values of exercises depend primarily upon their effects. The effects of exercise fall into the following three fields: 1. Anatomical. 2. Physiological. 3. Psychological.

For the anatomical and physiological effects, we have suggested the following classification:

MOST TYPICAL RESULTS

1. Local	Immediate	Mechanical	Muscular contraction—vasorelaxation
2. Local	Immediate	Chemical	Oxidation — Sarcolactic Acid CO_2 produced
3. Local	Secondary	Mechanical	Increase in size—increased vascularity
4. Local	Secondary	Chemical	Food storage—decrease fat and waste
5. General	Immediate	Mechanical	Body massage and jar—blood pressure raised or lowered
6. General	Immediate	Chemical	Transmutation and transfer of food waste and excretion
7. General	Secondary	Mechanical	Increased tone in all tissues — posture improved
8. General	Secondary	Chemical	Increased metabolism in all tissues

APPLICATION OF EXERCISE TO MEDICINE

The application of exercise depends upon the health consultant's knowledge of its effects, his knowledge of the various kinds of exercise, which correspond to his knowledge of the various items in the pharmacopœia, and lastly, it depends upon his skill in applying the right exercises in the right way to the life of his client. While each physician should have a skilled clinical assistant in this subject at his disposal, yet he cannot guide this assistant correctly without study, experience, personal observation and personal use of the exercises which are especially good for himself.

GENERAL HUMAN NEEDS OF EXERCISE

Anatomical.—It is a biological fact that man comes from an ancestry of quadrupeds, who have gradually

assumed an upright position, which is responsible for much structural deficiency. Assuming an upright position, the head tends to fall forward and downward, the spine to increase its curve, the ribs to drop and the chest to flatten; the lumbar curve is increased and the arch of the foot breaks down. These are called structural ptoses. They are the result of the relative inability of the body to fight successfully against the continual effect of gravity. They are a sign of insufficient vitality. This is usually called bad posture. Accompanying this structural ptosis is visceral ptosis. The heart, lungs, liver, intestines, in fact the whole body tends to slump downward, and the lower abdomen to bulge. This is also a sign of deficient gravity resistance, due to inferior vitality and muscular weakness. Circulatory ptosis, due to deficient splanchnic tone, accompanies these conditions, and we have the familiar asthenic complex. Properly selected exercise should be directed to the sustentacular muscles, which raise the chest, straighten the dorsal spine and reinforce the lower abdominal wall, overcoming the three classes of ptoses, structural, visceral and circulatory. The campaign against asthenia results in a man with an erect head, large chest and slim muscular abdomen. Without these characteristics, no approach to one hundred per cent. physical condition is possible. This must be explained to the health client. The proper exercise is selected and taught. He should return after a brief period and his posture should be retested. The comparative girth of chest and abdomen should again be determined and his improvement noted for his encouragement and the insurance of the continuation of his program. The exercises for this purpose can be found in some of the newer books written by physicians for this specific purpose.

Physiological.—The great physiological need for exercise is occasioned by the fact that our ancestors survived because they adapted themselves muscularly to the necessities of a vigorous motor life. For this reason fifty-five per cent. of the body weight is muscular, and more than half of the brain is concerned directly in muscular movement. Similarly, the whole organic equipment is designed to support an active muscular life. At present, the average man and woman do not get this activity. As a result, the organic equipment, running at under one quarter to one third its normal load, deteriorates and premature old age results from stagnation and selfpoisoning. Nine tenths of civilized men and women are for this reason inferior specimens of humanity, and inevitably destined to premature senility. This may be overcome by reestablishing habits of exercise by making it feasible, interesting and attractive. It is the health consultant's duty first to ascertain what the normal exercise program should be and to place the client enthusiastically on the road.

Psychological.—Our mental and emotional selves are adjusted to active motor lives and are relatively starved because of the deficiency of incentive and opportunity characteristic of civilization. The reason why men like to go hunting and fishing and enjoy games like tennis, baseball and basketball, which involves throwing, running, catching and hitting, is because these things were formerly paramount essentials to survival. If he cannot indulge in these, he does so vicariously by attending a baseball game, a prize fight, or listening to reports of these over the radio, or reading about them. Some daily newspapers carry from one to three pages of sport news for our vicarious participation in motor work. The same is true of recreation in general. The recreational life of the ordinary individual must be returned to the point near the normal if lives are to be fully sane and happy. A large part of the health consultant's duty is to seek opportunities for this active participation. He should know the gymnasiums, play grounds, skating rinks, coasting hills, tennis courts, hiking trails and camping places that are available for his clients. And he neglects his duty if he neglects this service. Incidentally, and most important, he should be conversant with them himself for his own purpose.

Standard exercise program.—While there are exercises which are best for every one, yet a general exercise schedule which can be utilized falls under the following headings: 1, Daily morning exercise; 2, daily walk; 3, workout; 4, Saturday afternoon; 5, Sunday holiday.

Daily morning exercise.—The daily morning exercise period should be brief, interesting and attractive, and directed definitely toward the individual needs. Several systems are now available.

The daily walk.—The daily walk should be graduated to the needs of the client. It should follow interesting roads with a definite objective. The best prescription to be written for a walk is to take a dog, a cane and a friend. The walk can be used to increase the chest expansion and improve posture. One of the best prescriptions is to fill the chest and then, on the next two steps, to take in additional little breaths; on the third step, to breathe out slightly—a rhythm of in, in, out, in, in, out, lasting for fifteen steps. Breathe regularly for fifteen steps and repeat.

The workout.—The workout is a period of active, perspiration producing exercise. Most men and women do not know what it is to perspire freely. This relieves the kidneys and sets into operation a normal organism seldom used. Nothing is more health producing although this prescription should be used with caution, the client to be referred to a gymnasium, tennis court, or other establishment, for this purpose, but not without previous investigation.

The Saturday afternoon.—For the indoor worker, nothing is more essential than to get out of doors into the space, where the human race was born and where it grew up. This requires a knowledge of surrounding country, and perhaps the organization of a hiking club. In one health clinic in New York city, the clients have been organized into regular hiking clubs, and the results are correspondingly excellent.

The Sunday holiday.—The same thing applies to the Sunday holiday. This opens a field of life construction in which there are at present practically no instructors. The physician who has health clients is the nearest instructor at hand and will find a great reward in fulfilling his duty.

Program.—In the all around program of exercise, there will be found both exercises which are formal in character—definitely prescribed for definite results—and the informal exercises of the game and athletic type. The latter, while more interesting and attractive, can never be made fully to give the practical corrective service that properly selected definite exercise can render.

SUMMARY OF THE COURSE ON PRECLINICAL MEDICINE

There have been presented in this symposium a series of addresses on the preclinical signs of disease in various fields of medicine. In no case has any speaker assumed to exhaust his field. In fact, they have frankly admitted the tremendous scope of the subject. The most important service that has been rendered is in calling the attention of the medical profession to the fact that there are a series of diseases, disabilities and forms of deterioration which only attack the middle aged and invariably have their effect on every one in later years, and lead to death. A study of preclinical medicine has already revealed the fact that a large number of these diseases—perhaps properly called incurable—can be either prevented or postponed. If this is the case, as it will increasingly appear to be from signs already apparent, we have a field of activity which will lengthen the average life, not many years, but many decades. It will put into the category of preventable diseases not only malaria, smallpox, diphtheria and tuberculosis, but nephritis, high blood pressure, myocarditis and diabetes. This result is to be accomplished best by scientific research into the preclinical signs of these diseases, which foreshadow them by a decade or more; secondly, by ascertaining with great completeness what methods can be used to obstruct their approach; and third, by convincing the public at large that they should obtain a health examination and a health service at the hands of a competent consultant. Fourth, and last, so to educate the medical profession that they shall be able to seize upon preclinical signs and successfully combat them. In addition to this, there is much and important service to be rendered to humanity in developing a mediocre physical equipment into a superior human being.

Evulsion of Hair as Experienced in Damascus

DOUGLASS W. MONTGOMERY, M.D.
San Francisco

Recently, while in Damascus, I had an unusual experience at the hands of a barber. After shaving he took a thin strong thread, and while holding one end between the teeth and the other with the fingers threw a loop in the middle of the thread. The loop was held apart on the fingers of the left hand, and was twisted so that it formed three or four turns on the length of the thread. By distending the fingers in the loop, and by pulling on the ends of the thread, he made the turns revolve rapidly, and in some way he managed to keep these rapidly revolving turns pressed against the face with one of his fingers. The hairs became implicated in the turns and were ripped out or broken. It must have required practice and dexterity to perform the operation, but there was no doubt of the result. He first performed this little operation in the hollow of the right earshell, causing both a surprise and a pain, a ripping sort of pain unlike anything I had hitherto felt, but by no means so stinging as in ordinary evulsion of the hair. After finishing with this ear he went over the right malar prominence, and by this time I was tired of the experience. On inquiry I was told that it was done as an extra fine touch, making the cheeks look cleaner than with a shave.

After shaving, the cut ends of the coarse hairs often show; if black, as black dots, or if gray, at first as dots of crystal, as mentioned by Henri Barbusse, and as they emerge further they give a frosty appearance, and in any case interfere with the velvety softness of the skin. Therefore a deep elimination of the hair, such as I suffered, is of course more thoroughly, more enduringly beautiful than the best shave.

Evulsion of the hair by tweezers has been practised from the earliest times, and in races with sparse beards, as, for example, the Chinese and the American Indian, it is practicable. With those races, however, which are bearded like a Skye terrier, it is another story.

Lummis speaks of the pair of golden tweezers, "the razor of antiquity," found hung by a cord about the neck of the mummies near Lima, and with which instrument to this day many of the aborigines of South America pluck out the scanty hairs by the roots, one by one (1).

Modern shaving in a reclining chair with marvellous soaps, hot water, towels, and a keen edged razor is a luxury, but Rosita Forbes in her journey in the Sahara mentions the case of an Arab, preparing to enter a desert town, being shaved by a comrade with a Gillette blade held in a pair of nippers. We are accustomed to think of the Romans as being luxurious, but I never see a line of Roman busts of senators and emperors with their smooth, dewlapped, atonic jowls without thinking of the broken glass said to be so frequently used by them to clear off an offending beard.

At no time throughout quite an extensive recent journey in Europe, in Egypt and in the Near East did I have the pleasure of reclining in an American barber's chair. Some of the barbers admitted having seen such chairs in the movies but did not have the money or enterprise to purchase one. As for the hot towels, those also were absent. As a lame substitute they subjected their victims to a prolonged use of the shaving brush, according to the old Scotch proverb, "Weel sapid (soaped) is half shav-ed," and in one instance in Budapest a superannuated barber was employed solely for this purpose, a strange preparation in the decline of life for entrance into the world where all the male celebrities are represented as being heavily bearded.

Instruments, Apparatus, and Clinical Notes

Treatment of Fractures of the Long Bones of the Lower Extremity

BENJAMIN T. TILTON, M.D., F.A.C.S.

New York

Traction by weight in treating fractures of the long bones of the lower extremity, particularly the femur, has been employed for many years. Of its necessity there should be no doubt, although there are still surgeons who rely upon a plaster of Paris circular splint, applied under manual extension, or extension on a Hawley or Albee table or with some similar mechanical aid. A method of this type cannot give satisfactory results in the majority of cases, as displacement of the fractured surfaces usually occurs beneath the plaster, followed by overriding and shortening, no matter how skillfully the plaster splint is applied.

Up to recent years traction by weight, while showing far better results than the plaster splint method, has not been entirely satisfactory owing to the fact that traction has been exerted through the use of adhesive or mole skin plaster applied in the form of strips to the skin. To the ends of the plaster strips, traction is made by weight and pulley or by attachment to the end of a Thomas splint. This socalled skin traction has required frequent changing on account of detachment of the adhesive plaster from the skin, from the constant pulling. Furthermore, irritation of the skin and even ulceration very frequently result especially in hot weather. Even when the skin traction is well borne the amount of traction on the lower fragment is usually not sufficient to overcome completely the overriding and shortening. Some shortening, usually not less than one half an inch or more, has been the rule in fractures of the femur treated by skin traction. End to end approximation of the fragments has in my experience practically never been attained.

Good functional results are not uncommon in spite of the shortening, but in many cases the patient has to wear a thicker sole to compensate for the diminished length of the injured limb. The ideal anatomical reduction, viz., end to end approximation, has been attained by open operation and for this reason some surgeons recommend this in place of the closed method. The danger of infection, however, associated with this method, especially in the hands of those inexperienced in the technic of bone surgery, makes this an undesirable routine procedure. It is only in very exceptional cases that it is indicated.

Since the advent a few years ago of skeletal traction in place of skin traction, much better anatomical reduction has been attained. The original Steinman nail which was driven transversely through the condyles of the femur above the joint, was not satisfactory on account of the danger of infection from the presence of a foreign body in the cancellous tissue. The introduction of the calipers has largely obviated this danger and hence they are much to be preferred. The sharp ends of this ice tong shaped instrument are inserted through small incisions in the skin and driven by a mallet into the cortex of the femur just above the condyles and direct traction is thus made possible on the lower fragment. If sufficient weight is applied the fragments can not only be brought end to end but they can be drawn apart leaving a gap between. It is well to use a heavy weight at the outset for traction and then gradually diminish it in accordance with the progress of the case. This requires the use of a portable x ray apparatus, to check up the position of the fragments. A gap between the fragments means that the weight must be materially reduced.

Any lateral or anteroposterior displacement of the fragments can be corrected by lateral traction, a coaptation splint, or by a small sand bag placed over the projecting fragment. These cases require constant supervision and adjustment, but the excellence of the anatomical results obtained repays the time expended.

If for some reason such as open wound or abrasion it is not advisable to insert the calipers into the lower end of the femur, they may be introduced into the maleoli or the sides of the os calcis. Definite contraindications to the use of calipers in the femur are:

1. A fracture of the lower end of the shaft with one or more fissures involving the condyle and knee joint. There is danger here of infection of the joint with resulting ankylosis, amputation or death from sepsis. All of these consequences have occurred to my knowledge.

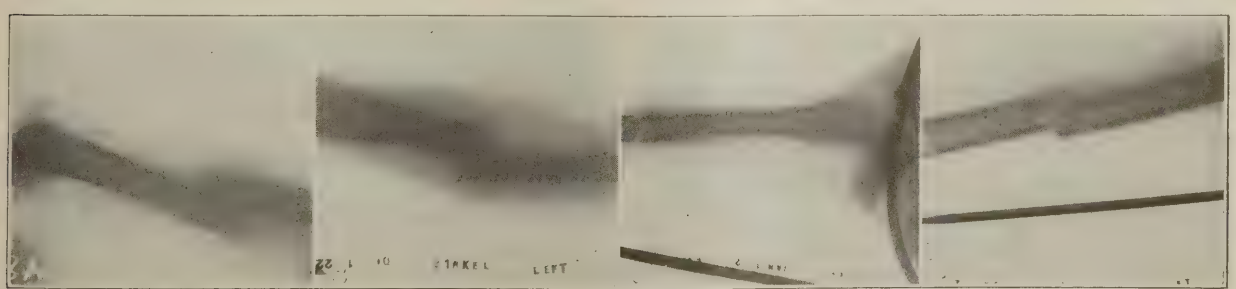

FIG. 1.—Case I. Fracture at middle of shaft of femur. A—Lateral view; note the marked overriding. B—Anteroposterior view; note the lateral displacement. C—Anteroposterior view (after insertion of calipers); the overriding and lateral displacement have been corrected. D—Lateral view; note the absence of any shortening.

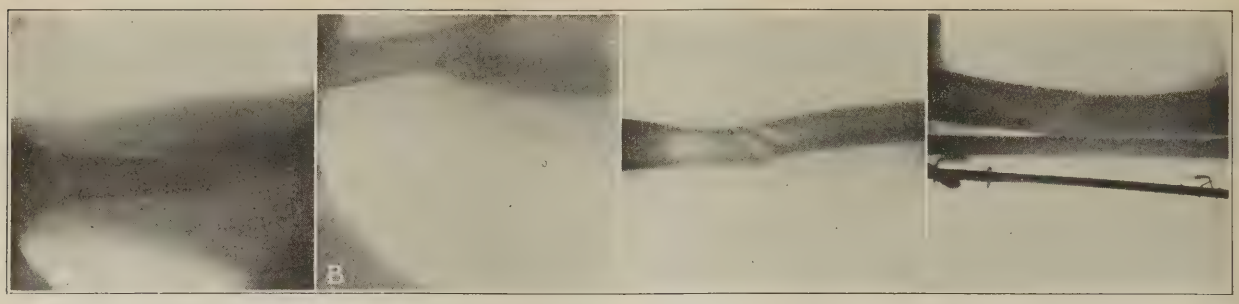

Fig. 2.—Case II. Fracture of femur at junction of middle and upper third. A—Anteroposterior view; note the marked overriding. B—Lateral view; note the angulation and overriding. C—Anteroposterior view; after application of calipers. D—Lateral view.

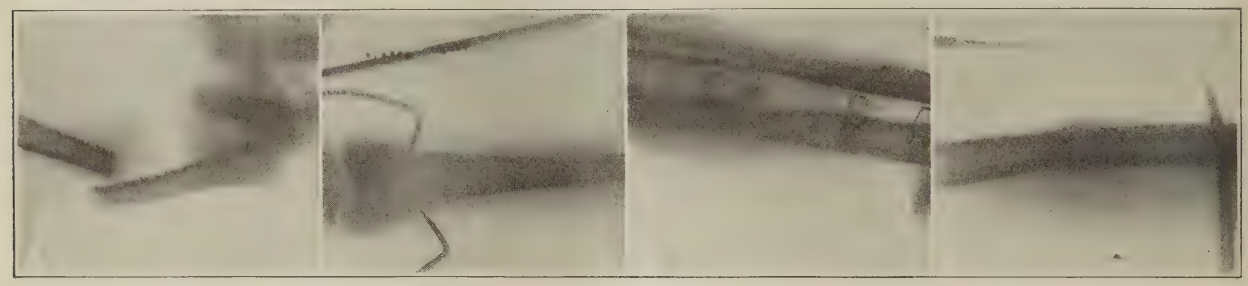

Fig. 3.—Case III. Fracture of middle of shaft of femur and dislocation of hip. A—Anterior view; note marked overriding and angulation; also dislocation of head of femur. B—Anterior view; note corrected position and calipers in proper position. C—Lateral view; note slight separation of ends of fragments. D—Anterior view. The dislocation was reduced before application of the calipers.

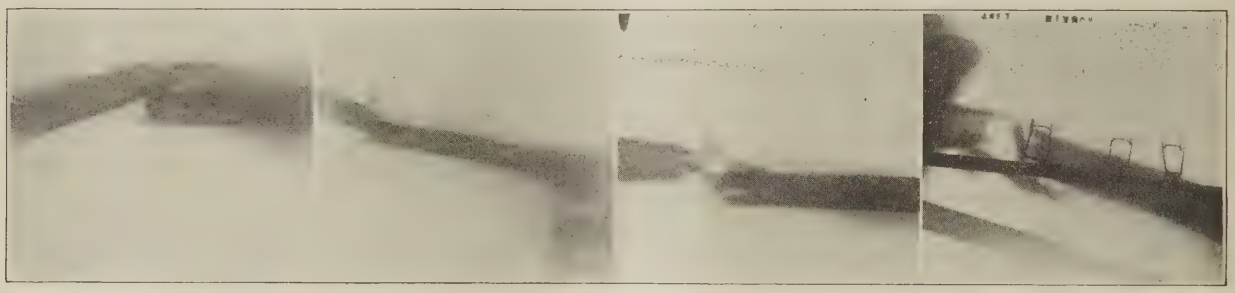

Fig. 4.—Case IV. Fracture of shaft of femur at junction of middle and lower third. A—Lateral view; note overriding. B—Anterior view; note angulation. C—Lateral view; after insertion of calipers; note wide separation of ends of fragments. D—Anterior view; note correction of angulation.

Fig. 6.—Case VI. Fracture of middle of shaft of femur. A—Lateral view; after application of skin traction. B—Anterior view; after application of skin traction. C—Lateral view; after substitution of caliper traction for skin traction. D—Anterior view; with caliper traction.

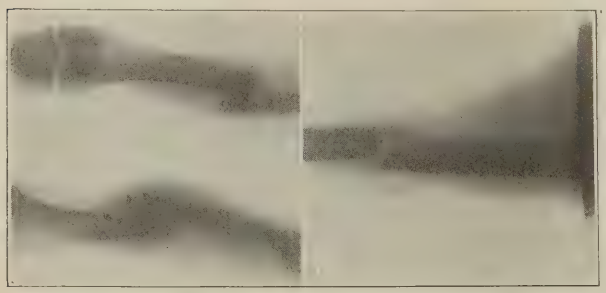

Fig. 5.—Case V. Fracture of middle of shaft of femur. A—Anterior and lateral views; note extreme overriding. B—Anterior view; after insertion of calipers; note slight separation of ends of fragments.

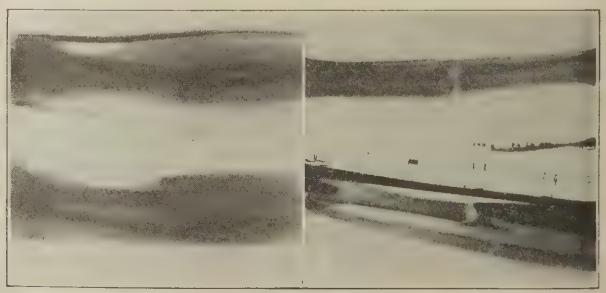

Fig. 7.—Case VII. Fracture of tibia and fibula. A—After application of plaster of Paris cast; note the marked overriding. B—After substitution of caliper traction at the maleoli, for the plaster cast; note correction of the overriding.

2. An external wound or abrasion at or near the point of insertion of the calipers. Infection of the wound may contaminate the caliper wound resulting in cellulitis and even osteomyelitis.

Should infection appear in the caliper wounds, the calipers should be removed immediately. They can then be inserted at some other point such as the malleoli or sides of the os calcis.

Thus far we have had in mind the recent cases of fracture in which the ends of the fragments are freely movable. Caliper traction is also very valuable in cases of one or more weeks' standing when callus formation has already begun, and when considerable effort is necessary to make the fragments freely movable on one another and when there is considerable contraction of the soft parts. Under these conditions the calipers can bring the lower fragments to a level with the upper and overcome a shortening and deformity which threatened a bad result and a possible open operation. In this way the indications for open reduction have been still further restricted. It is necessary before inserting the calipers to thoroughly mobilize the ends of the fragments under the general anesthetic. A heavier weight than is usual in recent cases should be applied at once.

There are some points in technic which are of importance for the successful use of the calipers. In the first place the insertion of calipers should be regarded as a major operation, and the same aseptic precautions carried out as for any operation involving bone. I am opposed to the custom of some surgeons of inserting these with the patient in bed in a ward where asepsis cannot be so complete as in an operating room. The skin should be prepared by shaving and application of a soap poultice the night before. Before making the two short lateral incisions just above the condyles, the skin should be drawn up with the left hand so that the cuts retract downward on release of the hand. In this way the lower angle of the incision is not pulled upon by the calipers causing pain. The sharp ends of the calipers are driven through the cortex of the shaft by a mallet just above the condyles. The lower extremity is then suspended from a Balkan frame on a Thomas splint and the necessary amount of weight usually about twenty-five pounds, attached to a cord running from the calipers over a pulley at the end of the bed. A portable x ray picture is taken at once and any necessary correction then made in the amount of extension or abduction. The apparatus should be frequently inspected and other x ray pictures taken from time to time.

It will be necessary to keep the calipers in about four weeks. If they are not well borne beyond this time they can be removed and skin traction with a small weight substituted until the union has become solid.

Device for Making the Bucky Diaphragm Comfortable

CHARLES EVERETT HAINES, M.D.

New Rochelle, N. Y.

The type of Bucky diaphragm which stands, a sharp edged block, on the röntgen ray table, often causes discomfort or even pain to patients. In the usual röntgen ray laboratory pillows are used against this discomfort, and it is true that they do help somewhat to level the surface on which the patient lies. However, pillows have a habit of bulging and depressing, and of getting out of place and in the way, so that they are a matter of great annoyance. Besides, they rarely save the patient from at least some contact with the sharp edges of the diaphragm.

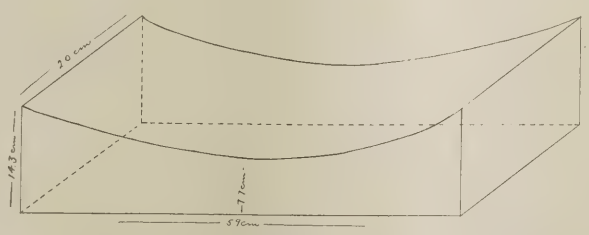

Fig. 1.—Author's device for making Bucky diaphragm comfortable.

I had to cope with a Brady Potter Bucky diaphragm. I devised the following simple arrangement for the comfort and relief of patients. I had the hospital carpenter construct six hollow wooden blocks, each fifty-nine cm. by twenty cm. by fourteen and three tenths cm. The length of each block corresponds with the width of the diaphragm; the height at either end of each block corresponds with the height at either end of the diaphragm; and the width of one block added to that of the five other blocks and to the length of the diaphragm make up the entire length of the röntgen ray table. The upper surface of each block is concave to correspond with the concavity of the diaphragm, making the height of the block at the centre of the concave surface seven and seven tenths cm. The blocks are covered with felt.

These blocks placed at either the head or the foot of the röntgen ray table fit next to the diaphragm and thus give an uninterrupted, even surrface on which the patient may lie. If the diaphragm is placed in the middle of röntgen ray table, three blocks should be placed at the head and three at the foot. If the diaphragm is moved towards the head end of the röntgen ray table, one or two blocks, or perhaps none, should be used at the head end, and the rest of the blocks at the foot end. Thus the diaphragm may be moved freely, a shorter or longer distance, as it may seem necessary, always maintaining a smooth uninterrupted surface on which the patient may lie.

Experience has shown that the width of the blocks as given, twenty cm., is convenient and practical, narrower ones being unnecessary for the general purposes of röntgen ray work, while wider ones might

sometimes be inconvenient or clumsy. However, slight variations of the dimensions of the blocks may be necessary in order to conform to the measurements of the röntgen ray table, and will not, of course, detract from their value of the blocks.

In the röntgen ray laboratory where I introduced these blocks, they have proved a boon, not only to patients, but to nurses and doctors as well; and they have made for orderliness which the old method of using pillows did not permit.

181 North Avenue.

The Indications and Technic for Removal of Excessive Subcutaneous Abdominal Fat.—Aime Paul Heineck (*Northwest Medicine,* June, 1925) asserts that, in properly selected cases, large masses of fat can be removed from flabby, sagging, fatty abdominal walls when the excessive fat deposit causes great annoyance and discomfort, determines manifest disability, constitutes a physical handicap, or becomes an unbearable social handicap. Resection of large masses of fat is also justifiable and serviceable in the obese to lessen the tendency to hernia; in operating for hernia in the obese; as an associated step in many abdominal operations; as a preliminary step in other abdominal operations, and in cases in which the careful fitting and wearing of orthopedic apparatus is not otherwise feasible. He also claims that the operation is simple of execution, quickly performed, and always devoid of immediate or remote danger to the patient. Yet he calls attention to the fact that fat is a tissue of low vitality, so that special care must be taken that there be little or no accumulation of serous or sanguineous fluid between the flaps.

Systematic Preoperative Vaccination with Delbet's Vaccines.—E. Blanco-Acevedo (*Bulletin de l'Académie de médicine,* May 19, 1925) reports good results from this procedure in preventing the postoperative flareups of infection in apparently uninfected tissue which sometimes gravely compromise the issue in otherwise promising cases. Embolism after simple operations and infection after metallic osteosynthesis exemplify such cases. The author has been carrying preoperative vaccination in all his cases for four years. The vaccine, prepared according to Delbet's published directions, is polyvalent and contains staphylococci, streptococci and pyocyaneus organisms. It often induces a rather marked constitutional reaction, with which its efficacy seems to be related. More constant results were obtained with this vaccine than with others. Three subcutaneous injections of two to four mils of vaccine at three day intervals are given, and three days are allowed between the last injection and the operation, except in case of emergency. Four groups of cases in which the procedure proved especially helpful are mentioned The first is that of apparently uninfected cases of simple uterine fibroma or small ovarian cysts; these cases are highly susceptible to the least superimposed infection. The second group is that of tumors of the cervix subjected to extensive hysterectomies of the Wertheim type. In these cases there is nearly always a more or less manifest infection of the parametrium; under the vaccine treatment the inflammatory manifestations subsided and the operative wound could regularly be closed without drainage. The third group is that of the cases treated by intrauterine applications of radium, which, as is well known, are often followed by pronounced septic disturbances. The fourth group comprises fifty cases of metallic osteosynthesis; of these, only one showed a local inflammatory reaction which necessitated reopening of the wound, and this case proved to have been the only one in the series in which, through an attendant's mistake, no preoperative vaccine had been given. The author's combined statistics include 389 cases of laparatomy receiving vaccine, without any deaths or complications with phlebitis or embolism. This series included 220 hysterectomies for salpingitis or fibroids; ten myomectomies; 114 conservative operations, salpingectomies or ovariectomies; thirty fixations of the uterus, and fifteen Wertheim operations. The appendix was removed at the same time in eighty-five per cent. of the cases.

Recent Improvements of Technic in the Surgery of the Spinal Cord.—R. Leriche (*Presse médicale,* May 30, 1925) deems the sitting posture introduced by de Martel an important improvement. At all levels of the cord, but especially in the cervical region, this posture, by almost completely eliminating venous bleeding, makes exposure of the spinal cord easy and facilitates intrameningeal manipulations and suture of the dura. Thanks to this position, the author was able to remove a growth at the level of the third, fourth and fifth cervical vertebræ in a very stout, shortnecked woman. Another improvement is the use of local anesthesia, preceded by morphine or some other narcotic. All spinal surgery can be carried out under this method; the patient does not suffer and can himself facilitate the operation. A third feature is subdural, extraarachnoid exploration of the cord and spinal roots. The author adopts this procedure regularly before opening the subarachnoid space. It is more easily carried out with the cord than in the brain, and permits of precise topographic study of the lesions, the spinal roots and tumors being in their normal relations. The operation causes less injury to the cord, with corresponding improvement in the prognosis as to life and function.

Clinical Observations on the Effect of Insulin.—Reginald Fitz (*Northwestern Medicine,* August, 1925) says that on the whole, our present knowledge in regard to the immediate effect of insulin upon the diabetic patient is fairly comprehensive. Insulin lowers the blood sugar concentration by increasing the rate of sugar consumption or storage in the body. Insulin acts as an alkali in diabetic acidosis by preventing the formation of acetone bodies and by thus liberating previously bound base. Insulin spares the breakdown of body protein. Insulin enables the diabetic patient with acidosis to hold back water and to become hydrated. For all these reasons insulin is of the greatest possible value in the practical management of diabetic cases. Whether insulin can cure diabetes is for the future to decide. For the time being we must take a conservative and somewhat skeptical point of view on this phase of the insulin problem and must wait for the reports of a large number of cases carefully followed for a far longer period of time than has thus far been possible.

Historical Medicine

Hints of Medical and Other Interests in the Odyssey

JONATHAN WRIGHT, M.D.

Pleasantville, N. Y.

Man has arrived at his high estate very largely through curiosity. It is a mighty faculty of the mind in the hidden springs of the evolution of man. Curiosity is the mainspring, observation depends on it. Memory and reason turn out the finished product. The stories of the sea were manufactured to feed the curiosity of dwellers by it and mariners on the Mediterranean told the stories of the Odyssey, which Homer put into his immortal poems. They owe their existence then to this fundamental factor of the human mind. This product of this factor has outlasted a thousand cities and ten thousand book markets. Millions of tales have been forgotten, but still the tricks Circe and Calypso played on Odysseus, the stroke Odysseus played on Polyphemus, run through the printed pages of every civilized land. Long after Homer's time, far into our own, men sit at feasts for the crumbs that drop from his table. To these are still invited from afar as honored guests (1a), "workers for the people—a prophet, a doctor, a shaper of spears or a pleasing minstrel." Even the swineherd Eumæus understood that and the doctor gladly returns to such feasts.

Five or six years ago I left Telemachus drinking a cocktail in the columns of this journal (2a), stirred by the fair hands of Helen of Troy, and such a cocktail! "She cast a drug into the wine whereof they drank—a drug to lull all pain and bring forgetfulness of every sorrow" (1b), and all but three thousand years later a poet in another land sang:

". . . . . vainly I had sought to borrow
From my books surcease of sorrow—
Sorrow for the lost Lenore.

and he cried to his soul:

"Quaff, oh quaff this kind nepenthe," and when we become old both our own and the blind poet of Chios sing to our souls. The *nepenthe* of the Homeric line appeals to us in that of Poe. What kind of drug was it? "Whoso should drink a draft thereof, when it is mingled in the bowl, on that day he would let no tear fall down his cheeks, not though his father and mother were dead, not though men slew his brother or dear son with the sword before his face and his own eyes beheld it. Medicine of such virtue and so helpful had the daughter of Zeus, which Polydamna, the wife of Thon had given her, a woman of Egypt, where the grain giver yields herbs in greatest plenty, many that are healing in the cup and many baneful" —but most are both—and the civilized nations of the earth, as I write, in council assembled, Christians by profession, are attempting to find a way to minister to the bane of primitive orientals for their own profit in the very drug Helen had from the oriental woman. Helen drank it herself to show it was void of evil, but we know better.

This, we can only take it, was a hint at opiates. If it was opiates Helen put in the drink for Telemachus, was it to make him forget his father of whom he was seeking news at the court of Helen's lord? She does not say so, but it seems rather queer to us westerners, unaccustomed to the taste of the orientals hitting the pipe with its hashish and opium gum. We see no reason why Helen wanted to hokus the drink of her departing guest, a favorite device for crimps to get their victims aboard a ship, in practise for centuries at Mediterranean and other sea ports. Whether Helen's stirrup cup for Telemachus contained opium or not we have clearer grounds for the belief that it is what Circe used in subduing the wolves and lions around her to house pets, "bad medicine she gave them," the poet says (1c) (Fig. 1). Though Circe dwelt in a house of polished stones and there are other indications all through the Odyssey of a civilization far advanced in some directions in Homer's day, though Helen in Lacedemon, despite the fact she was a lady with a past, was housed magnificently by Menelaus, who appears as a rather dull and vain rich fool, we find these ladies, both of doubtful virtue, dabbling in drugs. In it all we can not but think of the exaggeration around a new thing, the dazzling fame of a strange new drug or cureall which stirs poets to sing of it and the press to be full of it. We can imagine, until archeology or history tells us better, that as Homer wrote the dazzling fame of some somniferous drug called "moly" or something else was spreading around the shores and stealing through the islands of the eastern Mediterranean, for he was singing and wandering there, too. They are digging up pipes today in the palaces of the kings of Kish and I am fain to believe the fair Helen after flirting with many men had hit the pipe as well as looked long on the wine when it was red. Her end fancy pictures to us must have been a ghastly one, we who have memories of the morgue and the manhandled bodies of such charmers, pricked with needle points on every purple space which could be reached, a horrid sight at which every hardened man, like an

Fig. 1.—Circe and Odysseus (Flaxmann)

old hospital intern now grown older still, has a right to shudder—despite the poet's idea of her death—some one's lost Lenore. Helen has appealed to most readers as the heroine of the Iliad and it has seemed to me one reason for believing that Homer wrote the Odyssey later in life is that she is but a faded heroine in it. Age has had time to know the evanescence of beauty and charm and in old age as one looks back beauty and charm cluster most thickly about the sweet simplicity of some quite natural and ordinary maiden like Nausicaa and a rustic simpleton like Eumæus the swineherd. They would be quite out of place in the Iliad.

Just a line more and we read of the Nile land, where the poppies grow that yield the nepenthe. "There each man is a leech beyond all human kind, yea they are of the race of Paeon." In another essay (3) I have cited Herodotus alluding to the Libyan sheep bearing lambs with horns already sprouted at birth and more recently in the same journal I have pointed out that Homer, who lived, Herodotus says, just "four hundred years before him and no more" records the same thing. Homer is exclaiming in an exaggerated way, with poetic license, "there every man's a doctor." Here again Herodotus echoes Homer, minus the poet's license—there "all places abound in physicians" (4). Here it is Herodotus records, too, the specialization of Egyptian practice, lending further precision to what Homer had recorded four hundred years before. On many other occasions the evidence has been pointed out of the dependence of the medicine of the Greeks on that of the Egyptians before them. They in all likelihood had eye doctors and throat doctors and gynecologists before Homer was born in Chios or Smyrna and all Homer's world knew of it up through Syria and Palestine as far as Troy. Here we find much later the Greek poet and still later the Greek historian recording it a thousand years after the Shepherd Kings had entered Palestine and conquered Egypt. Asiatics, they seem to have been, from the south, and the Greeks we flatter ourselves were at that time being formed out of northern blood from beyond the Danube. It may have been that the northern torrent met the southern tide of immigrants then along the fertile shores of what was later to be ruled by Ionian cities, until the Persians came. Old Egypt was crumbling even then. She handed on to the Greeks her medical lore and the Hippocratic writings furnish abundant internal evidence of her influence.

It is somewhat conjectural, no doubt, but we may be permitted to believe that the Polydamna, wife of Thon, Homer speaks of in the Odyssey, was the wife of Thoth—of him who now in our Egyptology figures as the Egyptian Hippocrates or Æsculapius. Homer in the Odyssey in his exaggeration that all the Egyptians were physicians but gives voice to the semi-civilized people who think all dwellers in a highly civilized land are wise men and all wise men are physicians necessarily, for that is the contact of ignorance with science. Just as the press or the poets have led or have expressed the views of impoverished Europe that all Americans are rich, so Homer exclaims: "All Egyptians are physicians." Now the gods of Greece being all powerful and omniscient must know the medical art. We can not deny the logic of this sequence of priestly vauntings and this was the sentiment behind some of the early critics of Homer who blamed him for blesphemy, where he makes Odysseus cry out he wished to God he could send Polyphemus to Hell, bereft of soul and life as well as of his only eye (1d), but at least not even his father Poseidon can cure his eye, thank God. A very natural expression of sentiment, I am sure, for one who, standing among his trembling friends, had seen the giant (Fig. 2)

"Seize, crush and devour a brace of the Greeks
As a Welshman would swallow a couple of leeks."

Fig. 2.—Odysseus inebriating Polyphemus (Flaxmann)

If a man were permitted to blaspheme at all while "poking a spar in his forward light," it certainly was on such an occasion as the adventure of Odysseus and his companions with the Cyclops, when he so narrowly himself escaped the cannibal. But as has been said the innumerable commentators of Homer have had, among the early ones, those who blamed him for representing Poseidon as possessing no medical or surgical skill (5), but Homer found defenders who declared that while a number of the gods, Phoebus and Paeon among them, were skilled in the healing art, Poseidon, spending so much time at sea, I suppose, was not. Antisthenes and Aristotle, it seems, both advanced this excuse for Homer.

Somewhere, in some commentary on Galen, in these columns perhaps, I have alluded to the belief of ancient physicians that olive oil was good for the skin and bad for the stomach. Nowadays in our northern climes we love to smear the mayonnaise over our shrimp and chicken salads to grease the stomach and we refuse to clog our skin pores with unguents. The ladies of course put it on their lips to draw kisses, but elsewhere unctions are much out of style, entirely so in society, I think, and much so in medicine, but not so in Homeric days:

"All too long has my skin needed anointing," says Odysseus (1e) when the servants of Alkinous gave him oil for his brawny shoulders which had for days buffeted the salt waves as he swam through the breakers around Phaeakia. So what we find in Galen we find in Homer, too. His idea was the skin needed it. He was a southerner and the blazing sun on the bare body kept the olive oil from being like tallow there. The Africans and others naked in the tropics still use it on the skin and sweat it out and I have no doubt in hot lands it serves a better purpose there than it does on the gastric mucosa.

Radiotherapy at Low and Moderate Voltages*

ARTHUR U. DESJARDINS, M.D.

Rochester, Minnesota

The expression deep therapy has obtained such widespread currency that one would almost be led to consider it a permanent addition to our professional language. And yet, to specialists in radiology it carries no meaning, because any form of radiotherapy is more or less deep, according to the spectral composition of the rays employed. As generally used the term deep therapy is supposed to mean high voltage röntgen ray treatment, but as a synonym it is a rank misnomer. Many physicians say deep therapy when they do not mean high voltage röntgen ray treatment, and much unnecessary confusion is thus engendered.

A few years ago when high voltage röntgenotherapy came into use, many radiologists thoughtlessly concluded that a new era had been reached, and that this new idea in röntgen ray treatment was a heaven sent, automatic and certain way of curing all human ailments. Consequently there was a stampede for high voltage apparatus, and manufacturers were kept blissfully busy. Less powerful machines were discarded in the mad rush for the latest thing, and in a short time the new mills were grinding their gory grist. Every form of disease was subjected to high voltage röntgen rays. Socalled deep therapy became the symbol of a new army of standardized radiological crusaders. Thought and common sense seemed to have disappeared with the discarded equipment.

Since then the force of inexorable realities has had a decidedly sobering effect on many radiologists, but others are still far from home and apparently unable to obtain their bearings. I do not wish to decry the use of the short wave length röntgen rays generated at the higher voltages. On the contrary, they have proved most useful in dealing with pathological conditions with which we had been quite powerless to cope heretofore. Tumors that formerly were uninfluenced by röntgen rays produced at lower voltage became more or less susceptible to treatment with short wave length röntgen rays. But if this is admittedly true, it is likewise true that conditions readily amenable to long or moderate wave length rays have not shown a like susceptibility to rays of short wave length. For instance, many diseases of the skin easily curable by röntgen rays of relatively long wave length do not respond to rays of short wave length. Many of us have failed to understand that, like any other form of treatment, röntgen ray treatment must be adapted in quality as well as in quantity to the effect desired, and that, according as we are dealing with a condition at the surface or at varying depths beneath it, we must select the portion of the röntgen ray spectrum which will be absorbed most completely at that level. For it is well known, though imperfectly understood, that only those rays that are absorbed by the cells produce cellular alterations. Unabsorbed rays are quite inert, so far as any effect on tissue is concerned.

During the last five years many radiologists have equipped themselves with high voltage röntgen ray generators. This step was a perfectly rational one, but instead of reserving short wave length ray treatment for suitable cases, many committed the blunder of subjecting to such treatment every form of disease supposedly amenable to röntgenological treatment, regardless of its nature and location. My opinion that this is not sound radiotherapy is partly confirmed by the published reports of a few radiologists who have been too honest to deceive themselves.

There are great differences in the many pathological conditions susceptible to röntgen ray treatment. These differences may be based on the relative depth of the lesions or on their very nature, and correct treatment must be adapted to the conditions obtaining in each case. To attempt to treat a case of ringworm of the scalp in the same way and with the same dose as a case of cancer of the uterine cervix is not scientific radiotherapy; it is pure empiricism and smacks of quackery. The tendency toward standardization has been carried too far. The effort to standardize generating apparatus and methods of measuring doses is highly commendable and should be encouraged by every possible means; but in treating disease it must be borne in mind that the body and its pathological disturbances are not and can never be standardized. It is just as wrong to treat epithelioma of the skin and carcinoma of the bladder with the same dose of röntgen rays as it would be to treat all cases of

*Read before the Chicago Röntgen Society, October 9, 1925, Chicago. Section on Röntgen Therapy, Mayo Clinic.

malaria with the same dose of quinine. The results in either case are not likely to be the best. Belot has recently said, "There can exist, in principle, as many different radiotherapies as there are wave lengths in the x ray spectrum." However, for practical purposes, radiotherapy may be applied at low voltage, at moderate voltage, or at high voltage, thus making possible the use of different proportions of the röntgen ray spectrum so as to take full advantage of the selective absorption of cells. Low voltage is between fifty and one hundred peak kilovolts; moderate voltage, between one hundred and one hundred and fifty peak kilovolts, and high voltage, between one hundred and fifty and two hundred peak kilovolts or more. Of course this is an arbitrary classification and subject to such future modification as therapeutic application and development may require.

In the treatment of diseases of the skin röntgen rays generated at approximately eighty peak kilovolts are generally the most useful. Filtration may or may not be used, depending on the degree of thickening of the lesions. Since it is the aim to have the skin itself absorb the greatest possible amount of the rays, unfiltered rays are usually preferable. This applies to benign as well as to malignant disease, the only difference being in the dose, which must be varied according to circumstances. Thus, in an ordinary case of acne vulgaris, rays generated at eighty peak kilovolts are generally used, and either 0.25 skin unit weekly or 0.5 unit every ten days or two weeks is given. However, if the lesions are notably indurated it is sometimes desirable to increase the voltage to one hundred peak kilovolts, and to employ one millimetre aluminum filter. In ringworm of the scalp in which the aim is to bring about a uniform temporary epilation, 1.25 skin units of unfiltered rays at eighty peak kilovolts are very effective. In dealing with more resistant lesions, such as warts, callosities, and keratosis, rays of the same quality are employed, but the dose is increased to from two to four skin units. The same is true of basal cell epitheliomas unless the thickness of the lesion and the accompanying induration make it necessary to increase the dose still more, or to employ some filtration plus an increase in dose.

Great care must be exercised in dealing with diseases of the skin. Treatment requires experience and thorough knowledge of the capacities and limitations of one's apparatus, as well as accurate methods of measuring the different elements that enter into the dosage. Two chief methods of measuring doses are in use: one largely employed by European radiologists, and the other more commonly employed in the United States. In the first method small discs or pastilles of barium platinocyanide are used. Röntgen rays cause these pastilles to change color; the change in color can be compared to a standard furnished with the pastille outfit, and the dose be thus determined. The method requires much practice and experience to make one sufficiently expert and accurate. It has the disadvantage of bringing in a considerable personal variation in reading the changes in color.

The second method does not require a special apparatus, but it does require test exposures on the skin of human beings under carefully controlled electrical conditions. From such tests a standard skin unit is established, after which it becomes merely a simple arithmetical problem to calculate any dose required.

Pathological disturbances well below the skin or even deep in the body respond well to rays generated at a voltage below one hundred peak kilovolts: enlargement of the thymus in infancy, for instance, and simple lymphatic hyperplasia. It is well known how responsive the tissues and organs in early life are to slight stimuli. As little radiation should be used as experience shows to be necessary to obtain the result sought. If röntgen rays produced at eighty or one hundred peak kilovolts are sufficient to cause a satisfactory regression of a markedly enlarged thymus, more penetrating rays should not be used at the risk of causing undesirable changes in other structures. The dose, likewise, should be kept to the necessary minimum. Unnecessary saturation of the organism with röntgen rays is no more desirable than to inject into it a quantity of any foreign substance beyond the minimal amount required for a specific purpose.

MODERATE VOLTAGE

Certain disease conditions underlying the skin, such as manifestations in the lymph nodes of simple inflammation, tuberculosis, and lymphoblastoma, and certain malignant neoplasms, such as malignant testicular embryoma, require röntgen rays of somewhat greater penetration. For these conditions treatment at moderate voltage is used, because it is necessary to employ rays that will be absorbed, not so much in the skin but in the underlying structures affected. This requires the use, not only of higher voltage, but of a certain degree of filtration to eliminate from the röntgen ray beam as much as possible of the long wave length rays which would only serve to interfere by their unnecessary action on the skin.

ILLUSTRATIVE CASE

CASE.—A man, aged forty-nine, registered at the Clinic February 18, 1925, complaining of weakness and pain in the left thigh of five months' duration. Seven years previously the lymph nodes of his neck and groins had become swollen. Under röntgen ray treatment this adenopathy had subsided but every few months thereafter the nodes had again enlarged, and he had been forced to submit to röntgen ray treatment repeatedly. Three years previously he had noted a small swelling just above the left elbow; this had gradually increased in size during the following year but had not affected his general health. Indeed, he was well enough to play through an important series of tennis matches. In July, 1924, he began to lose strength, became pale, and was distressed with pain in the lower third of the left thigh, which gradually swelled. He undertook the heroic measure of fasting for twenty-three days and lost twenty-five pounds. Subsequently he regained a few pounds but continued to lose strength, and the pain in the thigh did not abate. In August, 1924, röntgen ray treatment of the left thigh brought some relief and the swelling partly subsided. However, at about this time a gradually increasing dyspnea supervened.

On examination moderate bilateral adenopathy of the cervical, axillary and inguinal nodes was found. There was also extensive retroperitoneal and mediastinal adenopathy, with hydrothorax filling the right pleural cavity almost completely. In the left arm were two tumors pressing on and distorting the

bone. Röntgenograms of the lower third of the left femur showed an apparent destructive process, probably atrophic in origin, from the pressure of a tumor which previous röntgen ray treatment had caused to melt away. March 5, 1925, a node from the left supraclavicular region examined microscopically revealed lymphosarcoma. The patient was extremely ill and for a time it was doubtful if anything could be done for him. However, March 11th, after the aspiration of two thousand seven hundred c. c. of fluid from the right pleural cavity, the dyspnea was considerably relieved. An extensive course of röntgen ray treatment was then given, but it was divided over a period of ten days so as to minimize the tendency toward systemic reaction. To have attempted high voltage treatment under the circumstances might have been fatal. Consequently the first course of röntgenotherapy was given under the following technical conditions: voltage 135 peak kilovolts measured by the sphere-gap method, F. S. D. sixteen inches, and filtration either four or six mm. of aluminium. The areas treated with four mm. aluminium filtration received five ma. for twenty minutes, while those treated with six mm. aluminium received five ma. for thirty-five minutes. The treatment was directed to both sides of the neck, axillæ, both groins, the left arm, the mediastinum, the abdomen and the left thigh. Crossfiring was employed wherever feasible.

Almost from the start of the treatment the patient's condition began to improve. The remaining fluid in the right pleural cavity was absorbed spontaneously. The adenopathy everywhere diminished and he began to gain in weight and strength. When he was examined April 15th the swelling of the lymph nodes had largely disappeared or had become much reduced. The large mass of retroperitoneal lymph nodes which had been palpable previously could no longer be felt. The pain in the left thigh also had vanished. Between April 16th and 21st the patient was given a second course of röntgen ray treatment, similar in most respects to that given in March; it varied in two particulars only: an additional field over the frontal region of the head was treated, because two small subcutaneous nodules had appeared in the upper forehead and scalp, and the abdomen was not treated, in order to cause as little systemic reaction as possible and to encourage further gain in weight and strength. Following this second course of treatment improvement was rapid. When he was seen May 20th he had gained ten pounds more. There was very little trace of the previously recorded adenopathy. Infection of the middle ear on both sides had caused a temporary slump in improvement but he had been able to throw this off and was again on the mend. He received a third course of röntgen ray treatment between May 23rd and June 4th and shortly afterwards started for London greatly improved.

I do not wish to imply that all cases of the diseases mentioned should be invariably treated at moderate voltage, because, besides the purely technical factors of the problem, other factors must be constantly taken into the equation, chiefly the condition of the patient and his ability to tolerate the therapeutic measures proposed. In the case cited I have stated the reasons which influenced me in arranging the treatment as described. In other cases it may become advisable to combine röntgen rays of different quality (different voltage and different filtration), certain regions being treated at moderate voltage, and others at high voltage.

HIGH VOLTAGE

In the treatment of the more resistant forms of neoplasm, especially carcinoma and sarcoma, the most important single item to consider, aside from the condition of the patient, is the factor of absorption. Long and depressing experience has taught that röntgen rays generated at low or moderate voltage are of little avail for large voluminous tumors at or near the surface; this is still more true of such tumors deep within the trunk. Indeed, too often such new growths prove quite resistant to röntgen rays, regardless of their quality. However, in those of a relative degree of susceptibility, we must employ rays of as short a wave length as possible, by increasing both voltage and filtration. The object in such cases is to bring about the maximal absorption of röntgen rays by the tumor cells; this is accomplished by raising the voltage to the highest possible limit, thereby increasing the proportion of short wave length rays in the total beam, and by filtering the rays through metals of high atomic weight, thereby eliminating from the beam the long wave length rays which would only serve to block our efforts by their dissipated influence on the skin and superficial tissues. Important as is this fundamental principle, sound practice often requires its modification to suit special circumstances. For instance, if the tumor is relatively young, the general condition of the patient good, and the prospect of a permanent cure is reasonable, we are entirely justified in applying the principle with the utmost thoroughness. On the contrary, if the tumor is extensive, the general health of its victim seriously undermined, and the most we can hope for is to check the unfortunate course of events for a time, the idea of high voltage röntgen ray treatment may have to be given up and more modest measures instituted.

In certain varieties of disease röntgen rays are known to have a definite, though temporary effect which tends to diminish as time and the frequency of treatment increases. In spite of this well known tendency, it has been the practice of some radiologists to treat such cases from the start with high voltage röntgen rays, with the inevitable consequence that, once the effectiveness of these rays has been exhausted, further attempts at treatment have been fruitless. It is much better, therefore, to begin the treatment of such diseases as leucemia with low voltage röntgen rays. As the spleen, lymph nodes and bone marrow become more tolerant of the rays and respond less and less to their influence, the voltage and filtration can be progressively increased. Effective treatment can thus be carried on for a much longer period.

In cases of fibromyoma of the uterus, treatment at high voltage is preferable, because one course, consisting of two fields, each receiving a three-quarter dose at two hundred peak kilovolts, will accomplish in two days as much as from three to six courses of treatment at moderate voltage, covering a period of several months.

Within the narrow limits of this paper I could not touch on the detailed application of this idea, but I have tried to give you enough to induce some of you

to reconsider the situation. I cannot emphasize strongly enough the point that radiotherapy means the therapeutic application of all radiations. The radiosensitiveness of living cells and the laws governing the absorption of röntgen rays by the cells are the two most fundamental considerations in radiotherapy. Therefore, instead of confusing the problem by idle speculation concerning possible factors the actual existence of which is doubtful, it would be far more profitable to our patients and to ourselve if we stressed rather the sound application of wel established principles. We must learn to select fo the treatment of each case that portion of the spec trum corresponding most nearly in absorption char acteristics to the level below the surface at whic the diseased structures are situated. Let us be full fledged radiologists and not merely radiologica mechanicians.

Medical and Surgical Diathermy

HERMAN GOODMAN, M.D.
New York

Recent medical and surgical literature contains many articles dealing with a new field in which American physicians have been leaders.

Men of international repute as surgeons using accepted methods, who have applied the knife to thousands of patients in past years, have become very enthusiastic regarding the future of a new surgery as it will be practised without the scalpel. This refers to a practically bloodless division of tissues by the electrical knife. The prospect of a knifeless operating room must, in addition, especially appeal to patients who had hitherto hesitated to undergo operations. The terror that formerly gripped the sufferer when the surgeon proposed an operation has shifted within the past decade, from the fear of the anesthetic to the fear of the knife. Now even this dread will have vanished with more general adoption of the newer electric method.

The opportunity for marked advances in surgery is brightened accordingly. The surgeon who in the past had been forced to hesitate or to refuse to perform an otherwise necessary operation because of the likelihood of meeting with uncontrollable bleeding, will henceforth find no cause for delay by using the electrical acusector. Use of the new surgical diathermy gives him an agent which in the hands of an experienced operator makes excessive bleeding practically impossible. The age of bloodless surgery has thus been brought relatively nearer.

Thus, surgical diathermy is utilized as a substitute for the knife and yet applied in such a way as to make an incision which rivals that of the most adept surgeon with the sharpest of keen blades. The depth of the electrical cut may be judged to a nicety as no pressure whatever is necessary. The tissue under the surgeon's eye practically opens as if at the command of "open sesame" of *Ali Baba and the Forty Thieves*. In practice the applicator need not actually touch the skin, for example, as the needles are poised over the desired spot; then the high frequency current in the human tissues rushes to meet the suspended needle, splitting the tissue instantly, cleanly. All surgical procedures in cavities that formerly required the steel scalpel may now be performed by the electric energy in this new method.

Surgical diathermy implies far more than merely the one use—just explained. The skilled operator, with electric energy thus applied to surgery, may coagulate the tissues; thus he is able to remove unsightly blemishes and other superficial growths o either a benign or a malignant nature. Such tissue which the surgeon treats in this manner become powdery mass which can be readily wiped away with out bleeding. The involved areas heal without per ceptible scarring. The structures underlying th field operated upon by this new method remain ster ile, as germs cannot find a safe lodgment there.

Dr. Howard A. Kelly, writing in the MEDICA JOURNAL AND RECORD on the new surgery, say of this use of diathermy: "I therefore welcome thi new method of coagulation as a great addendum t our technic, not only enabling us to do some thing better, but also greatly enlarging our field of benefi cial activity."

Other modes of application of diathermy aid i various medical diseases; among these pneumonia rheumatism (socalled), arthritides, and indeed man affections which had previously been resistant t medicine by mouth.

With the high frequency apparatus, other mode of application of medical electricity are possible. Th spark from the Oudin current is invaluable in cer tain diseases, and its use with vacuum tubes has useful vogue.

In this connection one should add that the use b laymen of toy outfits sold without doctor's prescrip tions to the unwary may involve serious risk. Ofte a selftreated person may delay too long with such vaunted cureall, and when at length he or she doe consult a physician, the condition which earlier migh easily have been remedied by proper treatment ha advanced too far for eradication, so that only pallia tive measures are now of use. Incidentally, the mod ern trend is away from this wrong tendency, a annual or semiannual periodical health examination disclose future diseased conditions in the incipien stage. Serious maladies or dangerous sequelæ t what are at first only mild diseases are thus nippe in the bud, so to speak.

We must not wander too far afield, though. Dia thermy, medical or surgical, has come to stay. Rea what Dr. Kelly has said:". . . we have here a re markably startling invention and innovation, fo probably the last thing any one ever anticipated wa that the time honored scalpel, badge of our office a surgeons, as it were, would ever find a successfu rival. How unsafe it is to prophesy." Further o he added: "Those methods are not to be learned com

pletely in a week or a year. They call for a careful attention to a new technic, for discriminating judgment in their application and for increasing boldness with growing experience. The concept is a new one."

In dermatology, a field in which I have a special interest, a number of conditions lend themselves admirably to treatment by this relatively new electrical agent. A list of the more common dermatoses may not be amiss: angioma, callositas, cicatrix, clavus, condyloma acuminatum, cornu cutaneum, dermatitis papillaris capillitii, fibroma, keloid, keratosis, lupus, lymphangioma, milium, molluscum, nevi, neurofibroma, verruca, and xanthoma. If the accessible malignancies are included in dermatology, one finds surgical diathermy ideal for basal cell epithelioma, melanoma, and those unfortunate instances of metastasis in otherwise inoperable prickle cell growths.

In the field of the genitourinary specialist, a wide usefulness may be promised. Such lesions of the external genitalia, as verruca, persistent lichen planus papules, granuloma inguinale, epitheliomas, and chancroid occur to me at the moment. Circumcision could easily be done. Meatotomy would be rendered bloodless. Cutting the frenum or gee string, indicated according to some authorities in certain sexual neuroses, would be the work of but a moment. Bipolar use at low amperage would be indicated in disease of the prostate, softening stricture, destroying papillomas inside the bladder through the cystoscope, as well as malignancies for which other methods would fall short. Whether the gonococci are as amenable to destruction, as some assert, to the current is difficult to affirm at this time. The urethra and other parts invaded by the Neisserian organism are ideal hiding places and I for one would not depend exclusively on a nongermicidal method. On the other hand the sequelæ or complications of gonorrhea, the epididymitis, the follicular infections, the veru montanitis, and the prostatitis, not to mention the arthritides, respond to these modalities, as a rule.

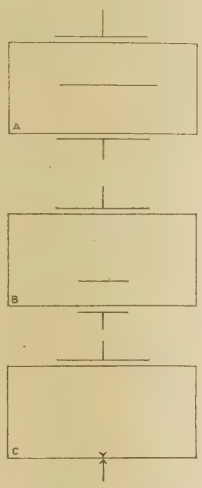

Fig. 1. — Diagram demonstrating the technic of applying high frequency modalities.

The proper application of high frequency modalities to the conditions just enumerated, depends on a definite knowledge of the existing pathology and an accurate working of the apparatus. No two machines delivering these modalities act in just the same manner. Hence, no one description of what button on the transformer, what space on the spark gap, or other seemingly definite technic can be arbitrarily insisted on here. Each machine must be tried out individually and after all, it is the clinical test that is of the highest value. Contact with a piece of fresh laundry soap will show the possible degree of dehydration as, also, the heat of the spark. Experience alone makes for perfection. No machine is fool proof.

A knowledge of physics is absolutely essential, as is that of construction of electrical apparatus. High frequency electricity, being an alternating current, has of course no polarity, thus differing from galvanism. The bipolar current of D'Arsonval generates heat according to definite physical laws. With plates of equal size, A, heat originates in the tissues at the site of greatest intensity, i. e., where the lines of currents cross. If one of the plates is smaller, B, the greatest heat is formed nearer to it. Use of a large plate with a needle as the second, C, electrode insures that the heat is greatest quite close to the needle point. Application of the monopolar high frequency of Oudin requires but a single electrode. The diagrams attached demonstrate the technic in a graphic way (Fig. 1).

18 East Eighty-ninth Street.

Diathermy in Bone Lesions*

WILLIS W. CAREY, M.D.

Fort Wayne, Ind.

It has long been recognized that of all the physical means used to destroy and stimulate heat has been the method of choice. Time, experience and education have done much to show us the fallacy as well as the merits of the different methods used. For our present day purpose we have selected that form, known as diathermy, over against that of some of the more ancient and prehistoric forms, as we would select an up to date automobile against the doctor's cart or gig.

We need go into no explanations as to what diathermy is, but a brief review of its physiological action may do us all good. Heat we consider under three heads: conductive, convective and conversive.

Conductive heat marks the first step; as hot stones; bricks and poultices, the most primitive, and later on the hot water bottle and electric pad.

Secondly, we have convective heat as shown by the application of the electric light—modalities.

Lastly we have conversive heat or that power to generate heat within the tissue itself and to which process has been given the name diathermy. How does it act? By experiment in laboratories it has been found that a current of high voltage and low amperage will give a greater heat power in the tissue, without destruction, than one of high amperage and low voltage, the skin offering more resistance in the latter. High frequency currents differ from other

*Read before The American Academy of Physiotherapy, at Atlantic City, N. J., May 29, 1925.

electrical currents in their voltage and follow the most direct path.

The heat gained in the surrounding parts is due to the circulation of the blood and lymph from the parts through which the rays travel. It might be well also to speak of the two actions of the diathermy current. One is destroying and is known as surgical diathermy, and the other palliative and stimulative and is known as medical diathermy. It is with the latter that this paper has to deal. To understand it better it may be worth while to review its physiological action. This is shown by the increase in oxygen and red blood cells to the part stimulated and from there carried to all parts of the body through the blood stream. It also stimulates the glands, absorbs the serum of the distended cell, relieving the hyperemia, lessens pressure and quickens the circulation, thereby helping to remove the irritant. It acts as a sedative and thus relieves pain. The rise in temperature and increased blood supply take place through the periosteum, epiphysis of long bones, as well as through soft tissue. The marrow that produces blood cells is made more active and cell production is increased, broken down tissue and invading organisms or toxins are now rapidly eliminated. Thus it not only inhibits the growth of the infection but lessens its productiveness and we have made our first step toward reconstruction or recovery.

The means of getting the current through that particular part must be gauged by the condition of the part to be treated.

In dealing with bone lesions we select small electrodes in order to condense the current in preference to large ones, as used on soft tissues where the current should be more diffuse. As to the quantity of current used the patient must be our guide. A sensation of heat that is fairly comfortable and pleasant to the patient should be the rule. Much of this result depends upon the application of the pads which must fit snug and evenly at all times.

Now a word as to what conditions are the most successfully treated by diathermy. Diathermy does not do the work alone but is one of the best and most trustworthy aids to restore function. When a man comes to us with a fractured leg he prefers a straight one but demands a useful one. The surgeon reduces the fracture and lets Nature and time do the rest. Diathermy helps Nature and shortens the time.

Diathermy enters into the economic field as well as the functional. No one would expect diathermy to revive dead bone or sequestra but after the surgeon has done his work it will help Nature in the work of restoration and the bone tissue will reproduce much more rapidly.

The better we understand patients and the disorders from which they suffer, the better we can help them. Therefore I would urge an x ray examination as well as a carefully gathered history of all patients. By this means we learn the amount of the patient's resistance. If we have to deal with a broken bone, we study the cause of the injury, the style of the splint, length of time worn, and concurrent diseases, such as syphilis, tuberculosis, diabetes and other constitutional disease which must be accorded their various treatment in conjunction with our work.

Last month I was called to see a young matron, thirty-two years of age. She had one child, eleven years old. She had never been seriously ill. For some ten or twelve weeks she had had severe pain in her left leg which localized itself in the middle of the thigh. She had received treatment for everything from inflammatory rheumatism to flat feet. At the same time she noticed that her left breast was enlarging rapidly but there was no pain, until her arm began to swell and she thought she had more rheumatism. She called in a surgeon who operated and found a carcinoma.

Some ten days later I was asked to treat the leg. Upon examination I found the leg swollen, edematous and excessively tender to the touch, at the junction of upper and lower third. I asked for an x ray. The same afternoon she was seized with a sudden cramp and the pain became excruciating. A large lump had appeared over this sensitive area and the x ray revealed a pathological fracture together with destruction of the bone tissue which proved to be a cancerous metastasis.

In tuberculosis of bone, affecting joints and long bones, we use the x ray as an aid in diagnosis. Comparing the joint with the opposite healthy one and if no lesion is found, ray some other parts of the body in which by experience we have found these lesions are more likely to occur. Points to be noticed are difference in thickness of the soft parts, the presence of blurring or cloudiness, and differences in density.

The length of time the condition has existed and the personal resistance of the patient can be judged in a way by the amount of new bone formation. In joints we expect to find bony ankylosis much earlier than in nonarticular surface.

In the spine we look for shrinking of the intervertebral discs and marginal changes in the bodies, this alteration in structure causing the kyphosis. The angulations are as a rule well marked. Luetic infections occur at all ages and we may have one or more joints affected.

It should be a routine measure to x ray long bones as well as joints under suspicion. A typical luetic joint shows marked swelling with thickening of the membrane and widening of the fluid space as compared with the normal, together with changes at the junction of the tendon and periosteum.

In the smaller joints we find early destruction of the articular surfaces. Then again we may not find syphilitic evidence, but this may be forthcoming if some of the long bones are x rayed. This is important in the line of treatment as against that of a general arthritis and spells success many times where if syphilitic treatment were not used no results would be obtained.

Gonorrheal arthritis more frequently manifests itself in the joints and early, has no definite pathology or x ray findings. Here again we have the widening out or bulging of the soft tissue. Later we find shrinkage of the cartilage, narrowing of the joint space and still later bony ankylosis together with localized areas on the margin of the joint proper. There may be calcareous deposits in tendons, most marked at their attachment, which are known as spurs.

In the acute infectious arthritis the x ray is of little help only as to its negativism. In the more

chronic cases we find atrophy of both bone and muscle. When the periosteum is destroyed we have bone proliferation, leading to exostosis; occurring in a joint, we have ankylosis. In the acute infectious types we have swelling and effusion in synovial cavities which, if not relieved, will soon be followed by bone changes. The severity of the infection has much to do with the patient's resistance and unless early combated the changes will soon occur. These changes are due to new involvement and offer the most unsatisfactory results. In those due to focal infection eliminate the cause and if not too long established much may be accomplished.

Taken altogether we must recognize the infection, curb the cause, give proper systemic treatment and to do this diathermy is one of the most powerful aids known. It acts in a normal physiological way, builds up, relieves pain, and inhibits growth of the infection, by increasing the blood supply, absorbs serum and makes it possible for Nature to do her own work.

Diathermy in a Case of Pneumonia Following Typhoid and Complicated by Diabetes

HARRY E. STEWART, M.D.

New Haven, Conn.

Case.—Mr. F. A. V., a banker, aged sixty, married, with six children. The patient's mother died of pneumonia complicated by diabetes at the age of sixty. There had been excellent general health throughout all adult life until six years ago when diabetes developed. The patient was one of the very first to receive insulin and has been under insulin and special diet for three years.

On December 1, 1924, the patient complained of general aches and pains all over the body especially in the abdomen, with slight fever and diarrhea. There were three cases of influenza in the house and his complaint was first diagnosed as influenza.

The temperature ran from 99° to 102° F. for two weeks gradually subsiding, when it again rose sharply to 102° and above. A Widal test was taken and found positive for typhoid. This second rise indicated his first relapse which ran from the fifteenth to the twenty-fifth day of his illness, during which time his average calorie intake was but little over six hundred. He had hallucinations, twitching of the limbs and marked traces of sugar in the urine. The second relapse lasted from the twenty-seventh to the thirty-seventh day when it remitted until the fifty-first day, at which time there occurred a third relapse of typhoid. He suffered at this time from a persistent carbuncle.

The temperature reached normal on the sixtieth day remaining so until the sixty-fifth day when a patch of lobular pneumonia developed in the left lower lobe, fever reaching 104° F. on the seventy-second day.

The patient was seen by Harlow Brooks, Evan Evans, G. Reese Satterlee, George Draper and Warren Coleman in consultation with Barnesby and Glafke in charge of the case. On the seventy-sixth day there developed a second patch of pneumonia on the right side. At that time his blood sugar was 187, white blood cells 6700, 85 per cent. polymorphonuclears, and the stool was negative for typhoid. On the eighty-third day there developed a third pneumonic process in the upper left lobe, which patch persisted, his febrile reaction never reaching 101° F. until the ninety-fourth day when I first saw him.

His general condition at that time was as follows: Pulse rapid and slightly irregular. Much pain in chest and coughing heavily. Extremely nervous, unable to sleep more than thirty minutes at a time. Expectorating brown bloodstreaked mucus, limbs twitching a great deal. Nervous reserve entirely gone. He was receiving forty units of insulin, fifteen minims of digitalis twice daily, and one half grain of codeine every four hours which was not quieting the pain nor inducing sleep. Urine showed two plus sugar, blood sugar 256, 53 per cent. carbon dioxide, red blood cells 4,210,000, white blood cells 8,200, 74 per cent. polymorphonuclears.

An anteroposterior diathermy by two five by seven flexible metal electrodes was given for twenty-five minutes at 1800 milliamperes, passing directly through the heart area. The appearance of the patient changed remarkably during the first treatment. The lines of pain and anxiety faded from his face, his pain remitted, there was an improvement in color and he slept two hours and thirty-five minutes following the first treatment, waking up greatly refreshed.

The treatments were repeated five times daily with a steady improvement in the character of the pulse. This point is emphasized because one or two writers have recently expressed the fear of ill results following diathermy through the heart in pneumonia. It might be noted here in passing that in some eighteen to twenty cases where the location of the pneumonia made the passage of the heat through the heart area desirable there was a markedly greater improvement in the quality of the pulse than that which followed the treatment of pneumonia in other locations.

On the fourth day of diathermy treatment this pneumonic patch which had remained solid for fifteen days, entirely disappeared to physical signs and the patient's general condition seemed much improved. Then his temperature rose suddenly to 103° and a fourth distinct patch developed in the left lung outside the heat pathway directed at the former process. In the opinion of the medical men then attending, this sharp febrile reaction to the fourth

pneumonic area was made possible by the rest and storing up of energy secured through the relief diathermy afforded him. The diathermy treatment was immediately applied to the new area, with a steady and satisfactory reduction in temperature and improvement in general condition. The area cleared up on the seventh day. Diathermy was discontinued on the tenth. At that time his blood sugar was 237, red cells 4,296,000, white cells 8900, polymorphonuclears 74 per cent., hemoglobin 87 per cent. The patient was receiving two thousand calories daily.

For two weeks his condition slowly improved, the lungs remained clear, when on the one hundred and twenty-third day of his illness another small area of consolidation in a new location in the left lung appeared. Diathermy was again begun and his temperature returned to normal and the spot cleared in three days after which diathermy was continued three times daily for two weeks, twice daily for an additional week, with large plates to cover the whole lung in the attempt to raise his local resistance and prevent a further process developing. This plan was entirely successful, his temperature has remained practically normal for five weeks, and the patient is now able to be outdoors.

SUMMARY

The history of this case was considered of especial interest since the age of the patient, the complications and the long duration of the disease made it an extremely difficult one. The very low resistance of diabetics to infections of all kinds and the fact that typhoid gave this patient a leucopenia, when to combat his pneumonia he needed a leucocytosis, were the two outstanding difficulties with which we had to contend. The favorable effect of diathermy upon his condition was so clear cut that in the opinion of the patient, his family and the physicians who followed the case it was the determining factor in his recovery.

420 Temple Street.

Physics in Medicine*

CHARLES F. STOKES, A.M., M.D., D.Sc., LL.D., F.A.C.S.
New York

My object in presenting this theme for discussion is to point out the changing attitude of the clinician toward his problems through the developing interest in the physics side of many of them. There is scarcely a large clinic today that has not a physicist on its staff. The physicist in a clinic, in addition to his routine duties, should keep himself fully informed of accredited work in physics as it has to do with medicine, not only in physiology and pathology, but in the adaptation of recent discoveries and inventions to diagnostic procedures, so that remedial measures along physical lines can be planned, when indicated, with an approach to precision, at least, technic bettered and a stimulus be given for the improvement of our present modalities. He should be a special correlating agent bringing to the clinic the results of recent researches in physicochemistry, biophysics and cytology.

ATOMIC THEORY OF MATTER

Man's mind of two thousand years ago was quite as good, in my opinion, as man's mind of today, but at that time he was hampered by lack of equipment with which fully to investigate his creative conceptions, and prove or disprove them. His environmental contacts were perhaps of a less stimulating character than those of today, and he did not have specialists to turn to, or draw upon for inspiration. He was probably less gregarious. Still such men as Lucretius have given us in fairly definite terms the concepts of an atomic theory of matter as developed two thousand years ago by Leucippus and Democritus. The poem of Lucretius entitled *De Rerum Natura,* (Concerning the Nature of Things) was translated and made into English verse about sixteen hundred years later by J. Evelyn and begins as follows:

> . . . . For I of Gods and Heaven will discourse
> And shew whence all things else derive their source,
> Whence Nature doth create, augment and cherish,
> To what again resolve them when they perish.
> What things in our discourse we Matter call,
> *Prolifique bodies,* and the seeds of all,
> Or if such terms do not the things comprise,
> *Prime Bodies* name them, whence all others arise.

While recording the views of others in which he firmly believed, Lucretius strove to convey the idea that if subdivision were carried out sufficiently one would come at last to the individual corpuscles, or to use another term, atoms, something which cannot be cut. Naturally he had no conception of the atomic theories of today for the physics laboratories of his time, if any existed, had not yet extended man's perceptual fields so as to bring him into closer contact with his problems. Lucretius did, however, believe that disease was conveyed by small particles, and this idea was taken hold of by Fracastoro at the time of the Renaissance, after reading the poem of Lucretius; these ideas were, however, in disfavor until Pasteur laid bare his germ theory of disease.

The conceptions of Lucretius were subjected to attack and ridicule and we find little allusion to them except perhaps in the works of Shakespeare where the word atom is used to convey the idea of something extremely small. Lucretius has come into his own in relatively recent times, for we find that with the enormous strides of the last quarter of a century, initiated by the unexpected discovery of röntgen rays, followed almost immediately by Becquerel's discovery of radioactivity, and the discovery of the subatomic corpuscle, or electron, by J. J. Thomson, and the later investigations of the ionization of gases, the torch has been carried farther, and tremendous possibilities have been developed not only for man's betterment in a material way, but through the appli-

*Read before the American Academy of Physiotherapy, Atlantic City, N. J., May 25, 1925.

cation of these principles to physiology and pathology, we are enabled to form more basic conceptions of disease, and plan more definitely for its prevention or possible cure.

And now let us consider what has led to these great advances, and what part has been played by the modest workers in the physics laboratories who have by the development of instruments of precision and amplification of our perceptual fields made it possible for us to see, weigh, measure and the like the objects of our interest. In Galileo's account of the invention of the telescope, he gives credit to an unnamed Dutchman for the idea that led to the development of his telescope and made possible the exploration of space, thus far, beyond the vision of man. While dynamics may be the field in which Galileo attained the greatest fame as a scientist, his name will always be associated with the invention of the telescope and astronomy. The development of a borrowed idea and its intelligent application led to the dawn of modern astronomy.

The title of perhaps the latest work of that distinguished British physicist, Sir William Bragg, is Concerning the Nature of Things (1925), the *De Rerum Natura* of Lucretius. Before, however, proceeding with the discussion of subatomic structure, let us consider for a moment what Dalton and the workers of his time had to do with the atomic theory.

The question of the nature of matter, the laws governing it and the like, had engaged man's attention for centuries, as these things have to do with the very foundations of the universe. The closer man came to the truth, a world of mobile corpuscles was revealed, and not a fixed mosaic. This led him into other fields, so that today, as our knowledge becomes more dependable, as Lukiesh says, we find emphasized the simplicity and unification of Nature. Modern knowledge has shown that chemistry is but a subdivision of the science of physics, just as optics and electromagnetism are parts of physical science. It is based on physical laws, not upon mysterious principles of affinities.

Boyle was the first definitely to state that substances were elements of matter, or combinations of them. Lavoisier established the principle of the indestructibility of matter and undertook crude but careful measurements of weight in chemical reactions. When Dalton later really made chemistry a science, he did so because the physical laboratories made it possible for him to determine weights and measures so that he was enabled firmly to found his idea of molecule and constituent atoms, and propound the law of multiple proportions, and develop the idea of relative atomic weights. Avogadro, in 1811, propounded a law that was destined to become a fundamental of the molecular theory of matter.

IONIC THEORY

The great Faraday found that by passing an electric current through various liquids, they were decomposed, the components possessing equal and opposite charges of electricity. How could Faraday have demonstrated ionization if the physical laboratory workers of his day had not provided him with the means of generating suitable electric currents? This led later to the knowledge that each atom has a definite charge and behaves in the presence of other atoms in accordance therewith.

In 1815 Prout basing his ideas on Dalton's atomic weights as amended by the more accurate work of Berzelius, suggested that the atomic weights of all the elements were the exact multiples of the atomic weight of hydrogen. Prout's hypothesis had a stormy career until quite recently when the modern theory of isotopes and inferences from radioactivity and the artificial disintegration of the atom gave it support. Ernest Rutherford, after years of study of radioactivity in nature, concluded in 1918 to attempt the disruption of the atom artificially by bombardment. The emission of an alpha particle from an atom is a spontaneous disruption of its positive nucleus according to modern views of atomic structure. Rutherford first bombarded nitrogen molecules by means of alpha particles emitted by one of the radioactive elements of the radium series and found that the disruption of the nuclei of nitrogen atoms resulted in the production of hydrogen nuclei. He also disrupted the atoms of boron, fluorine, phosphorus and aluminum with the same results.

Naturally this experiment gave added support to the theory that elements were built up on ions of hydrogen and electrons.

It would seem that the beginnings of things were relatively simple, still through lack of suitable equipment, through lack of training in scientific research and its principles, and by reason of various other deterring factors, it is only within the last two or three decades that man, although the desire existed, has been able to make satisfactory progress toward a better understanding of the beginning of things. One investigator must stand, and has stood, upon the shoulders of his predecessors, and in the end where noticeable advances have been made, it was usually because the period was timely.

THEORIES OF RADIATION

Let us consider Maxwell's wave theory of light. Who would have thought that the work of Oersted and Faraday in the early part of the nineteenth century was preparing the way for the present electromagnetic theory of light, and who could have visualized the unification of the wave theory of radiation and its extensions and modifications in the service of science? Following Maxwell, the mere mention of such names as Hertz, Newton, Herschel, Ritter and others, brings to mind service to mankind. While it is now known that every radiation produces a chemical effect, it was Ritter who, in 1801, found that the chemical action of sunlight extended beyond the violet end of the visible spectrum, and thus really discovered ultraviolet radiations.

In 1895 Röntgen discovered x rays, and three years later the Curies discovered radium, which was found to emit very short penetrating gamma rays, alpha particles, and beta particles, and recently Millikan has bridged the gap between the longer Röntgen rays and the ultraviolet region. It must be remembered that only those rays that are absorbed are effective and that it is only those wave lengths whose frequencies harmonize with the oscillations of the electrons of the tissues that are absorbed.

The saying that "seeing is believing," is one of the oldest and truest, in fact it has been through ex-

tended vision, largely, that man has become better acquainted with himself and his environment. The telescope has already been alluded to. The microscope has played a very vital part in the research work in pathology and bacteriology, and in other fields, and now the ultramicroscope has opened up many features of the vital field of the colloids. We are rapidly getting away from placing too much dependence upon observations of dead stained tissues in studying physiology and her erring sister pathology. Today we find groups of zoologists, biophysicists, physiological chemists and cytologists, carrying on their researches by means of living tissue cultures. Almost without exception they will concede that in the excitation transmission phenomena of protoplasm the first impulse is electrical, the second chemical and the third functional activity or structural change or both.

In the study of gross pathology the galvanometer is destined to play an important rôle, in fact in a recent public address Dr. George W. Crile made the statement that his galvanometric readings of the electrical potential of tumors were among his most dependable methods of determining the presence or absence of malignancy, stained laboratory sections notwithstanding.

Since the advent of the three electrode vacuum tube, physicists have devised many important instruments which depend entirely upon it for their success. The most minute currents may now be amplified through this device, until they are quite appreciable. Similarly high voltages and large currents can be controlled with ease. It is startling to realize that this device has been adapted to measure a change of distance equal to one hundred millionth of a centimetre, which is nearly the diameter of an atom of hydrogen. Temperature variations of the order of one sixteen thousandth of a degree centigrade fall within its range. As far as I know these devices have not been employed for diagnostic purposes, but that they will be so employed there is little doubt.

It is quite safe to say that all forms of matter are manifestations of electrical phenomena. Mathews states that all electrochemical phenomena are surface activities. Henderson quoting Bechhold says, "Now of all known physical structures there is none which rivals protoplasm in its fine complexity, and adsorption is therefore unquestionably a prominent agent in deciding its physicochemical constitution. Moreover, adsorption influences and complicates almost every process of chemical physiology, for no product of life is without its colloids, i. e., substances which are finely divided and therefore endowed with great surface areas. In truth, colloids are probably quite essential to fine complexity, and so to every conceivable form of life." It is interesting to note that in a cubic centimetre of tissue there is a little less than a square inch of surface area, while if the same bulk of tissue is split up into particles of colloidal dimensions, the surface area is close to an acre and a half.

In former papers I have stressed the point that the boundary line between chemistry and physics is fast being obliterated and in support of that contention have quoted the late Sir William Bayliss (1923) as follows: "It looks as if, before long, we shall not be contented with a statement that such and such a particular phenomenon is chemical but demand an explanation in terms of the physics of the atom." It is the valence electrons that have to do with the chemical activities of the atom. It is the valence electrons that have to do with physiological and pathological activities which lead to chemical changes. The correlation of the work now being done by biophysicists and cytophysicists should be more actively carried on by clinicians, and their associates. Many cherished traditions must be scrapped and I can assure you it takes a flexible mind properly to investigate, digest and assimilate the indisputable facts evolved by modern research. Nearly five years ago I announced the hypothesis that dynamic electrical equilibrium or preferably dynamic electron equilibrium in the human cell structure is a natural and normal condition indicating a state of health in that structure and that any upsetting of this equilibrium except through normal physiological excitations and transmissions, means an unnatural or abnormal condition indicating disorder or disease as the case may be. While this contention was set forth in the hope of bringing clinical medicine in line with the electron theory, what little comment it excited at the time and since has been largely antagonistic, I see no reason for changing my attitude. Of course in order that we may have a dynamically balanced potential, we must have a dielectric. In cell structure we find the semipermeable membranes playing the rôle to perfection. It is here we find our interfacial phenomena and forces active. Adsorption of colloids brings protoplasm on either side of the semipermeable membranes into intimate association with the heart of the electrochemical phenomena of the cell, on its particular side of the membrane.

THEORY OF OXIDATION

Mathews (1924) says in part in discussing oxidation, "That oxidation does involve, in all cases in which the process can be watched, the transfer of positive and negative particles or electrons, and that this is the essence of the process. Moreover, the more easily a substance gives up a negative charge the more active will it be as a reducing agent; and similarly the more easily it gives up a positive charge, or acquires a negative, the more active will it be as an oxidizing agent. Oxygen acts as an oxidizing agent because it has a great tendency to take away a negative charge (electron) from other substances and go over into the form of an oxygen ion, or of electronegative oxygen."

"The great importance of the theory from the point of view of physiological chemistry is that it shows at once that every oxidation in protoplasm is at the bottom an electrical process involving the transfer of electrical charges. In other words, an electrical disturbance of some kind, albeit possibly within molecular dimensions, must occur in every combustion of the protoplasm. It thus furnishes a point of attack of the origin of the electrical disturbances which are so characteristic of living matter of all kinds and enables an understanding of the disappearance of these currents when the respiration of the protoplasm is prevented."

Quoting Mathews further: "The energy of living things, whether it appears as heat, light, electrical disturbances or movements of masses, is due then directly, or indirectly, to the combustion of the car-

bon and hydrogen of the body by the oxygen of the air. Living matter is a combustion engine, with cylinders and connecting rods of molecular dimensions and provided possibly with a sparking device not so dissimilar in principle from that of an internal combustion or explosion engine. The discovery of the origin of the energy of living protoplasm in the combustion of carbon and hydrogen was one of the greatest, if not the greatest and most fundamental discovery in chemical biology."

I am inclined to turn this over to the physics department following the suggestion of Bayliss.

CELL STRUCTURE

Let us for a moment visualize cell structure without going into the details of cell chemistry. The nucleus is electropositive and acid separated by a semipermeable membrane from the electronegative alkaline cytoplasm. As far as I know the majority of pathological entities are electropositive in charge, i. e., the cytoplasm has been depleted of electrons, oxidation (cell respiration) is interfered with, hydration follows and the formation of lactic takes place. The cell is sick. The semipermeable membrane has become more permeable, the potential is lowered; response to impulses is feeble. Lillie has shown that calcium tends to hold up the semipermeability of the filmy cell membranes, in other words, to check permeability. The importance of thoroughly investigating calcium metabolism clinically is obvious.

If it is true that certain bacteria are cells without cytoplasm, in other words, wild nuclei, devastating the tissues and fluids of the body in their cytoplasmic activities, then it is not difficult to account for such pathologic cell changes as described, locally, generally or selectively. The electropositive bacteria deplete the electronegative cytoplasm of electrons and the healthy dynamic equilibrium is disturbed or possibly destroyed as the case may be.

APPLICATION OF PHYSICS TO MEDICINE

Through the application of the principles evolved by the researches in physics to clinical medicine, we are acquiring a more definite conception of the basic factors of health and disease. In my opinion out of the physics laboratories will come the greatest strides on the remedial side of medicine, indeed, the advance is well under way.

In dealing with a subject so vast as physics in medicine only a point here and there could possibly be discussed, still I have striven to lead the trail into the field of cytology or cytophysics if you like. No one has done more than Dr. Crile, of Cleveland, to correlate physicochemistry with clinical medicine. His addresses are always stimulating and instructive.

In *Science* on February 27, 1925, there appeared an abstract (1) of a paper by Heilbrunn in which he discusses the electrical charges of cells. Robert F. Loeb in April, 1925, wrote a paper on colloidal chemistry urging physicians to study intensively physicochemistry. Dr. W. J. Mayo, of Rochester, in a recent paper (3) says, "Physicochemistry of the human body concerns life itself. A proper understanding of these vital processes is necessary to every man who practices medicine no matter what his specialty may be."

To the physicists we owe much of our present armamentarium, still they will in the future, as they have in the past, look to us for suggestions along various lines leading to modifications of the several modalities to meet specific clinical indications. As hinted at above, we may soon have at hand instruments of precision for observation that may even reveal submolecular activities of one sort or another.

In planning a technic for treatment we should keep before us how energy can be transferred from one molecule to another as pointed out by Mathews, viz.: 1, by radiations in a series of pulses; 2, by the transfer of an electron; 3, by conductors of electricity.

If the foregoing is true then it must be in one, or more, of these ways that we accomplish results with our present equipment. That our modalities are too inelastic I believe will be generally conceded. That they are used too vigorously may not be so readily accepted. Pathological indications should be our guide. Thinking in terms of the strength of the bioelectrical currents of physiology and pathology, we should approach these current strengths in treatment, letting the factor, time, be the determining indicator in the amount of dose rather than an increase or decrease of amperage or voltage for our range of effects, in other words, employ sedation rather than intensity except in specific cases. We should strive for preventive or corrective effects, where possible, that is, to accomplish reversibility in pathological cells. Crile has stated that a rise in temperature of one degree centigrade increases oxidation ten per cent. and conductivity two and a half per cent. when using diathermy. Why go farther unless there is some specific indication? I am inclined the same way in the use of ultraviolet radiations, which is in line with the policy of Rollier in using solar light. Only use intensive treatment where indications for intensive treatment exist. Those of us who were using ultraviolet radiations four or five years ago little thought the field for their use would reach its present dimensions. The correlation of the researches in biophysics and clinical activities have accomplished this.

The practice of radiotherapy is in its infancy. The heavy haphazard doses of x rays and gamma rays will soon find their field of usefulness materially narrowed and the physics laboratories will accomplish this end. The small oft repeated doses of x rays are coming into their own. They reach cells undergoing mitosis and do not materially disturb normal cells. When mass destruction is necessary we have desiccation, electrocoagulation and the socalled endothermy methods, the last advocated by Clark, McFee, Wyeth, Howard Kelly and others. These latter procedures are revolutionizing surgery in many fields. The technic is entirely new and must be practiced repeatedly before skill is attained and this is only possible through a clean cut conception of the physics of the procedure. Physics is effecting a bewildering transformation in medicine and the outlook for humanity is distinctly better by reason of it. My plea is for a continued and closer correlation between physics and clinical practice which offers the most promising outlook in medicine today.

General Indications for X Ray and Radium Therapy

LEWIS J. FRIEDMAN, M.D.
New York

The series of events which led to the present perfection of technic in the use of radium and x rays need not be chronicled here. It suffices to state, however, that since the discovery of x rays by Konrad Röntgen, and of radium by Mme. Curie, exhaustive biological and biophysical experimentation has resulted in the standardization of this form of therapy so that its use has become universal and the results obtained are at times remarkable, if not actually startling.

It must be borne in mind, however, that radiation therapy cannot and should not be considered a panacea for all forms of disease, nor is its use entirely free from any sequelæ.

While the use of x rays is relatively harmless for diagnostic purposes, their promiscuous application as a therapeutic agent by the uninformed is bound to result disastrously. The radiations affect not only the disease, but also its host. An intimate knowledge of the physical properties of radium and x rays and a fair knowledge of pathology combined with good common sense, should be included in the curriculum of the wouldbe radiation therapist.

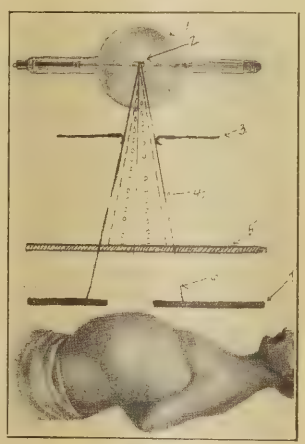

FIG. 1.—Semidiagrammatic representation of x ray radiation. 1, bulb; 2, target; 3, cone; 4, x ray beam of soft and penetrating rays; 5, copper filter; 6, penetrating rays only; 7, lead rubber shield.

TYPES OF RAYS

It would not be amiss to state briefly the physical characteristics and biological effects of the rays employed in this form of therapy.

Radium emits several types of rays, the most important being the beta and the gamma. The former are escharotic in their action and are analogous to the soft x rays. By the interposition of a suitable filter such as silver, platinum or lead for radium, and aluminum, zinc, or copper for x rays, the objectionable rays are to a considerable extent eliminated.

The gamma rays of radium consist of ultra short waves and are similar to a marked degree to the very hard and penetrating röntgen rays.

All of these rays can be polarized, which is of advantage, producing a spectrogram of the emitted radiation. Their wave length being measured with suitable instruments, the hardness of the ray is thereby determined and the kilovoltage computed therefrom. The shorter the wave length, the harder or more penetrating the ray. The gamma rays of radium, for instance, measure about .015 Å unit which is equivalent, approximately, to .0000000001 centimetre.

The power of these electrostatic waves to ionize air is utilized in an instrument, the iontoquantimeter, used in the estimation of doses, particularly of röntgen rays.

BIOLOGICAL EFFECT

It is a well known fact that normal and pathological tissues, as well as animal tissues, do not react alike to radium or x rays, some being readily susceptible, others mildly resistant, while a third group are only feebly if at all affected by any form of radiation.

Hirsch (1) classifies relative sensitivity of pathological tissues into six classes, namely, 1, very resistant; 2, resistant; 3, moderately resistant; 4, susceptible; 5, very susceptible; 6, most susceptible. "The more fibrous the growth, the more resistant; the more cellular the growth, the less resistant."

Then again, embryonal cells are more susceptible than the mature adult cells. An example of the former is the basal cell epithelioma, while the prickle or squamous cell type is quite resistant.

Radiation therapy may produce one of the following conditions or a combination of reactions may take place, depending, of course, on the dose administered.

1. Retard mitosis and enhance a normal metabolic process. This action is well illustrated in the treatment of leucemias.

2. Augment retrogressive metamorphosis, which condition is observed in the treatment of a persistent thymus, megalosplenia, and simple adenopathy.

3. The production of karyoklasis (nuclear destruction) can be demonstrated in the treatment of malignant neoplasms.

While this is a practical description of the ultimate results usually obtained, the progressive and successive stages that occur on irradiating lymphoid tissue are classically summarized by Ivy et al (2) as follows:

End of fifteen days: 1. Infiltration of red cells. 2. Proliferation of fibroblasts.

End of two months: 1. Gland diminished in size. 2. Less red cell infiltration. 3. Fibrous tissue stroma increased.

CHOICE OF EMANATOR

By the emanator, the author refers to radium or x ray apparatus. These have their indications according to the adaptability of the particular applicator and also according to the wisdom and best judgment of the therapist. The following are the determining factors which guide one's choice of the type of radiation therapy to be employed and incidentally aids in the expression of a probable prognosis:

1. *Biological structure of lesion.*—It is important that the type of lesion be determined microscopically where this is feasible. The necessity of ascertaining whether the epithelioma is of the basal cell or the squamous cell type has already been pointed out above. Cervical or uterine pathology frequently requires microscopic examination in order to determine the presence of malignancy. Hemorrhages occurring as a result of small fibroids may well be treated with the x rays. The additional use of radium, however, enhances the beneficial result. On the other hand,

if a malignancy is discovered, the application of radium locally to the point of tolerance and x rays from above should be the method of procedure. Breast tumors often require differentiation. The presence of a fibrous mass would simply indicate extirpation of the local lesion, whereas an adenocarcinoma requires a much more extensive resection and preoperative and postoperative radiation.

2. *Depth of lesion from skin surface.*—The necessity of determining this can readily be conceived in view of the fact that one must compute beforehand the amount of filtration necessary, depending on the depth of the lesion and the interposing structures. As an example of this, a malignant mediastinal tumor which requires deep therapy would have to be treated very cautiously on account of the presence of the thyroid, larynx, and trachea. Edema of the larynx may occur should a large radiation be given. The administration of radiation therapy is also limited by the reaction of the skin.

The use of x rays in the treatment of carcinoma of the esophagus has proved futile. Radium introduced through a gastrostomy opening may be effectual in selected cases, and should be tried in preference to other mutilating operative procedures.

3. *Accessibility to lesion.*—It is readily apparent that superficial lesions can be treated with either radium or x rays. The radium applicator is especially adapted for small skin lesions. In treating carcinoma of the tongue, for instance, while still superficial, the use of radium needles or radium seeds embedded in and around the tumor has proved to be of great value. The associated metastases to the cervical lymph nodes, on the other hand, require the x rays in preference to radium.

4. *Distribution of lesion.*—Small lesions can be treated with either x rays or radium, but diseases of the type of Kaposi sarcomatosis which is usually generalized is amenable to x ray therapy, which form of radiation can be distributed over a rather large surface. Myeloma is another type of disease for which x ray therapy is more adapted. The leucemias, Hodgkin's disease and lymphosarcomatosis are other examples for which the x rays must be used in preference to radium. In other words, the more disseminated the disease, the less is radium the emanator of choice.

5. *The economic problem.*—This can by no means be ignored. Radium element or the radium salt, the state in which this emanator is used in medicine, is extremely expensive. The production of emanation seeds and needles has reduced the prohibitive cost to a great extent. The therapeutic properties of the emanation are identical with those of the radium salts.

RÉSUMÉ

1. Radiation therapy is indicated in the following conditions: a. Paraplastic diseases. A few examples of this class may be mentioned: Adenomata simplex, fibromata (nevi, keloids, neuroma), lymphadenomata simplex, lymphogranulomatosis (Hodgkin's disease), leucemia (splenic, myelogenous). b. Neoplastic diseases: Carcinomata and sarcomata.

2. The biological structure of the lesion must be carefully studied so that the proper type of radiation, filtration, and dose be selected.

3. Preoperative and postoperative radiation therapy should be employed where the surgical removal of a neoplasm can be accomplished.

4. The use of radium in maximal doses for esophageal and cervical malignancy is a *sine qua non.*

Ultraviolet Rays in the Treatment of Some Nasal and Oral Conditions*

CHARLES R. BROOKE, M.D.

New York

It is true to state that the ultraviolet rays generated from the quartz mercury vapor lamps are invaluable in medicine and surgery. And it is also true that few physicians and surgeons realize the importance of this form of therapy. We must admit that much valuable information on the subject has been published as the result of experimentation, clinical study and observations, which have been and will be distinctly valuable in the development of this important branch of therapy. However, much of the work along these lines still remains in the experimental stage.

Space will not permit a consideration of the value of the ultraviolet rays in pathological conditions. My purpose is to concentrate on the value and the technic of the application of the ultraviolet rays in the treatment of some affections of the nose, mouth and throat. A clinical study has been made of over two hundred cases referred for treatment in a large general physiotherapy clinic during the past two years. This group of patients were suffering from acute nasal infections, nasal accessory sinusitis, hay fever, nasopharyngitis, acute follicular tonsillitis, incipient peritonsillar abscesses, Vincent's angina of the gums and throat, pyorrhea alveolaris and tuberculous ulcerations of the buccal cavity. Many of these cases were not treated by the ultraviolet rays alone but either preceded or supplemented by other appropriate physical measures and other indicated procedures. However, in some selected cases the patients were treated by local and general ultraviolet irradiation alone, the technic used and case reports to follow demonstrating the applications and the results achieved.

*Read before the American Academy of Physio Therapy, Atlantic City, N. J., May 25, 1925.

All patients treated were referred from the special nose and throat clinic, where thorough examination and diagnosis are invariably made, by a specialist; checking up of final results by the latter, after treatment, is the rule. A full clinical report of findings are submitted including x rays and reports of smears and culture growths. Before treatment is outlined a complete description is made of all clinical findings and subjective symptoms, these being accurately detailed in the case record.

The application of the ultraviolet rays in competent hands is safe and potent. The use of ultraviolet irradiations is a conservative treatment and will promptly clear up most infections of the nose and throat thus avoiding operative procedures in many instances. It is not my intention to discourage certain indicated operative procedures but experience has shown that far too many operations are performed on the upper respiratory tract and some do more harm than good.

The ultraviolet rays have a dual action in that the spectral bands are chiefly bactericidal from the water cooled lamp and chiefly biological from the air cooled lamps. The combination application of the rays emitted from the water and air cooled lamps form a basis for a rational treatment. The former applied locally to affected tissues to destroy infection and the latter to the surface of the body to be absorbed by the circulating blood thus increasing the general body resistance by favorable action on the blood.

The following information is given better to understand the action and reaction of ultraviolet rays, when applied to the tissues. There are two types of lamps supplying ultraviolet rays, air cooled and water cooled, and both produce ultraviolet irradiations from quartz mercury vapor burners. It must be realized, however, that their construction and therapeutic actions are different. (1) The air cooled lamp emits the longer light waves between 3,920 and 3,000 Angstrom units; the water cooled lamp, the short wave lengths, between 3,000 and 2,000 Angstrom units. The rays of long wave length emitted from the air cooled lamps are more penetrating than the rays of shorter wave length. They produce an erythema solare or sunburn more quickly and with greater intensity. They are dominantly biological, chemical oxidizing, relatively penetrating and a metabolic synergist. The shorter wave lengths from the water cooled lamp differ in being dominantly bactericidal, chemically reducing, relatively superficial unless given under compression and a metabolic depressor.

The ultraviolet rays from an air cooled lamp are readily absorbed into the capillary blood stream and carried to all parts of the body; they stimulate the phagocytic action of the leucocytes with increased formation of antibodies, and increases the quantity and quality of the red blood cells. When the physical resistance of a host is inadequate, it is a good practice to employ the general body ultraviolet irradiations from an air cooled lamp in addition to the treatment of local manifestations. The general absorption of the ultraviolet rays into the body increases tissue resistance and thus indirectly eradicates disease conditions. The ultraviolet rays from both lamps are bactericidal, the rays from the water cooled lamp being much more so, thereby destroying all forms of pathological organisms with a greater degree of certainty. It must be remembered that ultraviolet rays will not pass through ordinary glass, the pure fused quartz applicators being the best available conductors of ultraviolet energy. It is of importance to exercise extreme care in giving ultraviolet irradiations for they readily cause a burn of the skin or blister the mucous membranes. This fact, as just stated, is not particularly harmful but is not desirable unless a destructive action is indicated. This accident can be avoided by careful standardization of the lamps for the initial treatment and then proceed by gradually increasing the time of exposure and in case of the air cooled lamp varying the distance from the part. A lamp is standardized by finding out the distance from the part and the time required to produce a mild erythema solare or sunburn. The lamps should be permitted to burn for at least five minutes in order to reach maximum efficiency before treatments are given. The reaction depends on the type and intensity of burner and duration of exposure.

Some European practitioners favor the arc lamp as furnishing a greater volume of ultraviolet rays than does the quartz burner, the latter having far wider use in this country. The rapid wastage of the rods in the arc instrument on passage of the current, however, is a factor that would prejudice many physicians against its employment as compared with the more convenient quartz lamp. Authorities differ as to the relative value of the ultraviolet rays furnished from the arc and mercury quartz lamps. Although having had limited clinical experience with the arc lamp I maintain that the selective spectral band from the mercury quartz lamps yields richer ultraviolet rays than the carbon arc lamp which from its physical makeup yields a combination of all rays of the solar spectrum, together with heat production.

TECHNIC OF INTRANASAL APPLICATION

A Muehler nasal quartz applicator is attached to a watercooled lamp. The applicator at first is inserted gently as far back into the nasal cavity as possible, then is withdrawn slowly to permit of fractional irradiation to the entire mucosa. The applicator should not be pressed heavily or faced against the nasal membrane but allowed to lie gently upon the affected parts. In complicating sinus disease the applicator is inserted so that the tip approaches the affected sinus opening as nearly as possible. I have designed a special curved quartz applicator to accomplish this procedure and have found it particularly beneficial in directing the ray into the fossa of Rosenmuller which is often the site of infection. In using the straight flat Muehler quartz applicator the tip can be directed upward or downward as indicated. Duration of treatment at first lasts one minute to each nasal fossa; fractional irradiation, about fifteen seconds; this is increased a half minute each subsequent treatment up to five minutes or longer, fractionally applied. It must be remembered, in this connection, that most of the ray is emitted at the tip of the applicator, only stray rays bounding from the sides. Treatments should be accurately timed to avoid blistering, a contingency not specially harmful but not desirable.

The technic of application to the posterior nares and nasopharynx is made with the Sampson hay fever quartz applicator which is designed for this especial purpose, permitting a general irradiation to

these regions. This effort may start coughing or gagging by the patient, to be obviated by applying a solution of novocaine or cocaine about the uvular and nasopharyngeal wall. The exposures are made to the throat with Baldwin and Plank quartz applicators concentrating the rays to the affected tissues, always remembering thoroughly to expose the tonsillar and peritonsillar regions to avoid extension or complication of infections from the nose even though these tissues appear apparently free from disease. Duration of treatment to the nasopharynx and posterior nares is for one minute at the outset increasing a half minute each subsequent treatment. Exposures to the throat are given for the same periods, all treatments being accurately timed with the interval time clocks. All cases not complicated by acute sinusitis are improved after an average of three to four treatments and altogether relieved after five or six applications. When there is an acute nasal accessory sinusitis complicating nasal infections, and there usually is to some degree, the applications of ultraviolet rays are continued locally and generally to the body but in addition other physical measures, as the radiant light and heat, modified diathermy and intranasal high frequency using the nonvacuum insulated electrode attached to the Oudin current of a good high frequency machine should be used.

The technic of applications of ultraviolet rays for the treatment of Vincent's angina, pyorrhea and other infections of the gums, mouth and throat are carried out along the same principles except that the initial applications are more intensive beginning at two minutes' duration under compression to dehematize the part, which is succesively increased one minute for each subsequent treatment until a good reaction or slight blistering of the involved tissues is obtained. When this point has been reached omit treatment for four or five days to allow reaction to subside and then repeat the application. These applications are made with a set of three Sampson pyorrhea quartz rods which are made for this purpose. The affected gums are rayed anteriorly and posteriorly, sometimes six separate applications around one tooth, three anterior and three posterior being necessary.

Some cases of hay fever respond readily to the ultraviolet irradiations, although the primary factor still remains a mooted question; certain protein pollens with the presence of bacteria are, however, factors to be considered. The technic used for the relief of hay fever is a combined application of the ultraviolet rays to the anterior nares with a Muehler quartz applicator, to the posterior nares with the Sampson hay fever quartz applicator, together with a general application to the throat using a Plank quartz applicator. Applications are given in sequence beginning at one minute duration each, successively increased a half minute each subsequent treatment. Treatments, if started sufficiently early before the expected time of attack, will shorten, favorably modify and often abort the distressing symptoms. When treated during the attack intranasal high frequency is given for five or ten minutes to each nasal fossæ preceding the ultraviolet application. This combination treatment often gives prompt, efficient and adequate relief. The treatments at first should be given daily and later repeated as symptoms require.

I wish to emphasize the value of prescribing the general tonic ultraviolet irradiations from the air cooled lamps, preferring regional exposures beginning at two minutes' duration, with the lamp at a distance of thirty inches, in addition to the local intensive treatment with the water cooled lamp, in all infectious processes. This combined irradiation has been found to be an important adjuvant to increase the body resistance against infection, thus enhancing the building up of the "general rundown" system, which is often clinically demonstrated in patients suffering from nose and throat infections. Many foci of infection of the nose and throat can be cleared up by careful and judicious use of ultraviolet irradiation. It has been observed that ultraviolet irradiations will relieve pain when applied to mucous membranes. During the course of these treatments patients usually remain at their work in comfort. The progress in all cases is uniform and ultimately beneficial. The length of time to obtain maximum improvement varies in accordance with the individual case, duration of infection, its severity, extent of involvement and the bodily resistance of the host. Treatments should be given at first daily, gradually reducing them to alternate days and then to more infrequent applications as symptoms require.

The following cases illustrate the possibilities of the above described technic:*

Case I.—A. H. was admitted to the clinic August 9, 1923, with acute rhinitis, acute follicular tonsillitis with a beginning peritonsillar abscess. After receiving two intensive local ultraviolet ray treatments to the nose and tonsillar regions prompt relief was obtained and the peritonsillar abscess aborted. Technic: Three minutes' compression with the Plank quartz applicator to tonsillar areas and two minutes to the nasal mucous membranes with the Muehler quartz applicator. To make sure of avoiding a recurrence, two additional daily treatments were given and the patient was discharged as maximum improved.

Case III.—W. B. Pyorrhea alveolaris, receded gums and loose lower incisors teeth, three of which were to be extracted. The teeth were scaled prior to the ultraviolet ray treatment. Technic of application: Quartz rod applicators on a water cooled lamp, compression beginning at two minutes, successively increased one minute until a fourth degree erythema reaction or blistering was obtained to affected gums anterior and posterior. Patient received a total of twenty applications, after which the teeth tightened, and diseased areas disappeared. The three teeth which had been advised extracted were saved. Discharged as maximum improved.

In the treatment of pyorrhea, the ultraviolet ray acts as a destroyer of diseased tissues and a restorer of healthy tissues of the gums.

CONCLUSIONS

1. The ultraviolet irradiations are effective in the treatment of certain conditions of the nose, mouth and throat.

2. The ultraviolet rays are essentially bactericidal and biologic in action but vary therapeutically according to the wave length of their spectral bands and technic of application.

3. A carefully systematized technic of application

*Two additional cases cited by the author were omitted for lack of space.

must be employed to derive maximum value in the treatment of conditions of the nose, mouth and throat.

4. Ultraviolet ray therapy, by means of the modern quartz mercury vapor lamps, is an important addition to our treatment armamentarium.

5. Ultraviolet irradiations should always be administered by a trained physician or a competent aide or technician to achieve the best results.

Value of X Ray in the Diagnosis of Rectocolonic Diseases

J. F. MONTAGUE, M.D., F.A.C.S.
New York

Of late I have come to consider the barium enema study of the colon equally as valuable as the rectosigmoidoscope in the diagnosis of rectocolonic diseases. This opinion has been impelled by a consideration of a fairly large number of cases in which some element of pathology would have been overlooked had not a barium enema study been made in compliance with a definite indication to be mentioned later. That this high opinion of the value of barium enema study is not generally held must be evident when we note that such a study is infrequently made except in conjunction with a general gastrointestinal series. Even in the course of this, the examination of the colon often partakes of a perfunctory nature. It would seem, therefore, that the true value of the röntgen enema is not, as yet, fully realized. Perhaps the trouble lies in the fact that no worker in the field of rectal diseases, so far as I am aware, has, as yet, pointed out the definite indications for its employment or touched on the need of such an examination. It is with the object of calling attention to what I consider a neglected means for obtaining precision in proctological diagnosis that the following is submitted. We see cases of rectal or colonic disease in which the diagnosis is at best difficult and others in which symptoms are misleading. As instances of this situation the following case reports are cited. They will also serve to substantiate my contention that the modern requirements for thorough rectocolonic examination must include, if the condition of the patient permits, fluoroscopic and plate examination of the distended colon and similar examinations following evacuation.

Last February a lady forty-four years of age came complaining of pain high in the rectum and some soreness in the left iliac fossa. Associated with this was a rather suddenly developed tendency toward constipation. Rectoscopic examination showed nothing abnormal in the anus, rectum or sigmoid. Palpation of the abdomen elicited a tenderness over the iliac fossa and showed the presence of a mass. Under the circumstances, malignancy was suspected and a barium enema study of the colon was made with the result that a diagnosis of colonic stasis due to adhesions was made and the presence of cancer ruled out. Colonic irrigation and diet resulted in a cessation of symptoms.

Some time later a patient was referred to me with the request that I remove his hemorrhoids. As a matter of invariable custom I did a complete rectosigmoidoscopy which showed the presence of internal hemorrhoids, but no other lesions of rectum or sigmoid. In accordance with a lesson that experience has taught me I did not, however, proceed immediately to operate. The patient was over thirty-five and although apparently robust I suggested a barium enema study. The patient's family physician thought this unnecessary but I finally prevailed upon him. The barium study disclosed the presence of a carcinoma of the descending colon. Had I operated upon this man for hemorrhoids, what a great injustice would have been done him! By the barium study we discovered the growth at a time when operation was still practical and promising of success. At operation exploration confirmed the diagnosis. An annular carcinoma of the descending colon was found. His only symptoms had been a sudden tendency toward constipation and the discovery of hemorroids upon examination.

At another time a lady was referred to me with the diagnosis of carcinoma of the sigmoid colon and the request for my opinion as to its operability. The diagnosis was based on the fact that she had persistent bleeding from the bowel and had lost considerable weight. Rectosigmoidoscopic examination yielded no satisfactory evidence, the growth being presumed to be at a higher level. Barium enema study of the colon showed a marked diverticulitis but no evidence of new growth. Under appropriate treatment she was symptomatically improved and with care the diverticulosis should give her but little trouble. Eight weeks' observation has shown marked improvement in color, some increase in weight and all of this despite the fact that the patient is obsessed with the idea that she has cancer. From the latter illusion she was persuaded by an explanation of the x ray pictures.

The above mentioned cases are but a few instances where the x ray has been of incalculable value. In many others, to be sure, negative findings were made but even these have their value if only to give one a sense of confidence and assurance.

On the basis of a practice limited entirely to rectal diseases, I have come to certain conclusions in regard to the value of the röntgen enema in conjunction with diagnosis of these diseases. The conclusions may be briefly stated in the form of indications for barium enema study.

CONCLUSIONS

Barium enema study of the colon should be done in every case of hemorrhoids in a person over thirty-five, in all cases of chronic constipation, of suddenly developed constipation, of obscure bleeding from the bowel, of unexplained anal pruritus, in cases with a sense of weight or burning in the rectum, and finally in all cases of polyposis.

(*Continued from page* 685)

Without having it especially in mind in the allusions here and in other essays dealing with the Odyssey, tucked away in the pigeon holes of several editors, there has been disclosed what Homer was for the Greeks after him. All wisdom, law and literary art, even medicine and, we may yet see, religion found in him a master and in the Iliad and the Odyssey a court of last appeal. In the Ion of Plato's dialogue, Ion, the rhapsode, says: "Come, Socrates, see how I dress up Homer and improve him," but Socrates shows him out of his own mouth that he speaks of Homer, not from his own knowledge concerning the discourse of Homer or even concerning Homer himself, but out of the inspiration of God which Homer has transmitted to him.

I have had something to say, too, about the magic origin of the idea of drugs as exemplified in the Greek word, *pharmakos,* and perpetuated in our word for a drug store—a pharmacy, but returning to the parting scene at the house of Menelaus in Sparta and the charming Helen and the stirrup cup for Telemachus, it may be remarked in passing on to things indisputably magical there seems no reason, so far as I can make out, notwithstanding the suggestion of some commentators, to see anything magical in the posset given to the son of Odysseus. It was a hostess putting a little absinthe or vermouth or other bitters in a cocktail, but the thought we get out of the words is that an opiate in some form was an ingredient of the Homeric cup. Unlike the Iliad, in the Odyssey we get plentifully references to magical ceremonies with many features of which the study of modern primitive people has made us familiar. The Blood and the Soul (2b) I have alluded to elsewhere. We find traces of magical belief as to these among them, but Miss Harrison (6a) has, in her studies, done much to show the nature of the same trend of primitive thought as set forth in the Odyssey. Poetically it is a wonderful scene—the souls coming trooping to the pool of blood Odysseus made for them on his way to Hades that by sipping it they might again get some similitude of life (1f), and the shade of his dead mother does not recognize him at first, but when she had drunk of the blood—as Teresias did before he prophesied—she did recognize him. Incidentally in getting a vision of the physiology of the blood as the carrier of life we get the hint of the fading of the soul through loss of memory into oblivion and Homer becomes for us a religious teacher as well as a medical one. A taste of life brings back souls to consciousness like the transfusion of blood in the all but lifeless today.

Miss Harrison also quotes from the Odyssey (1g) a striking scene in which the ancient customs at the court of old Nestor of Pylos are set forth. A heifer is sacrificed to Athene. "It is a moment of high tension." The women raise their cry. "Life with all its might and sanctity is abroad. Then to make assurance doubly sure and to get the actual vehicle of life, the blood, they cut the victim's throat. 'The black blood gushed, the life had left the bones.'" We touch here the blood of life. The blood sacrifice and even the human life sacrified persisted at Athens, in all probability, to a surprisingly late era. Elsewhere in many places in the Odyssey, in the majority of places perhaps, the word sacrifice is used conventionally for the slaying of the animal for the feast, without further reference to any ritual. There seems, as Rogers remarks in a note to his translation, that the word in *The Frogs of Aristophanes* (1.757), *pharmakois,* refers to a ritual, which took the place of the blood sacrifice. There is much which could be cited from other evidence, but even here in the Odyssey it seems clear that the word *pharmakos* was once associated with much which had nothing to do with drugs just as now the word is associated with nothing that has anything to do with magic, although where we get the only unadulterated application of magic to healing in the cure of his wound, from the wild boar's tooth (1h) when Odysseus was a boy, the word *pharmakos* is not used. "With a song of healing they stayed the black blood."

Samuel Johnson.—A supper was held at Lichfield celebrating the hundred and sixteenth anniversary of the birth of Samuel Johnson, says the *Medical Press and Circular,* at which the immortal memory of the great lexicographer was proposed by Sir Charles Russell and drunk in punch passed by servants in contemporary attire. According to some, said the speaker, Johnson was a psychasthenic. His family history was faulty, and at an early age he presented symptoms which were diagnosed as scrofula. He was therefore taken to London to be "touched" by the Queen. MacLaurin has expressed the opinion, however, that his malady was probably not scrofula, but that the glandular swellings were due to "something in his scalp." For that he lived to be seventy-five seems to show that he suffered neither from tuberculosis nor syphilis, and if his glands had really been tuberculous, more serious symptoms than mere local scarring would have been present. Boswell diagnosed his patron's nervous ailment as a sort of St. Vitus dance, which, analyzed by MacLaurin, becomes psychasthenia, and accounts for what appears to him "the utterly unbalanced character" of Johnson. To illustrate this, he cites an incident in which Johnson carried to his own house the poor woman whom he found lying in the street, and, upon finding that she was one of those wretched ones that have sunk to the lowest depths, he saw to it that she was restored to health and encouraged to live a virtuous life. "This was just the sort of kind, impulsive and senseless thing," says MacLaurin, "that would seem so utterly natural to a psychasthenic, and so utterly silly to a normal man." We prefer, declares the *Medical Press,* the portrait painted by Sir Charles Russell of the great lexicographer's common sense, his humanity and charity, and his determination to do his duty.

Teeth in Olden Times*

THE HONORABLE WILLIAM RENWICK RIDDELL, LL.D.
Toronto, Canada

(*Concluded from page* 621)

It is a matter for astonishment that this animal is not found in all these Indies except in these mountains of Peru. For I have travelled the whole Kingdom of Mexico, all the Provinces and Kingdoms of Peru and many other regions of the West Indies, and I have never seen these animals except in the mountains of the Kingdom of Peru. . . .

We took nine stones out of the pouch of the first animal we opened; they seemed to be created by the bounty of nature from the juice of these health bearing herbs, which collects in that pouch. We opened also other animals which we killed, in all of which we found stones, more or fewer according to the age. It is to be observed, too, that only the animals which feed on the mountains produce these very valuable stones; for those which take food in the plains, as they eat herbs less salubrious, so the stones in them, useful as they are, are not equal in efficacy to those which are found in animals feeding upon the mountains."

The animals are now known as llamas. The stones were believed to be valuable in all cases of poisoning, in all affections of the heart and to expel intestinal worms; they were a prophylactic against poisoned arrows and admirable in dressing wounds—all imaginary, of course, even the vermifuge.

52. *Indi eos lapides magno habent in precio, eosque in Idolorum suorum delubris, quae Guacas vocant et alia etium preciosissima quaeque offerre solent veluti aurum, argentum, gemmas, monilia, animalia et pueros.*

53. *Dentes etiam confirmat et dealbat si saepius ea ea colluantur.*

The method of preparing the tincture or infusion is most elaborately described.

SUPPLEMENTARY NOTE

It may be interesting to give Celsus' observations on the Teeth—they are to be found in Book VII, cap. XII, sec. 1 of his *De Rê Medicâ:* In cap. XI, he speaks of certain diseases of the Mouth and in cap. XII he proceeds:

"In the mouth there are also some diseases to be cured manually—in the first place sometimes teeth are loose, whether on account of the weakness of the roots or of the defect by the gums drying up. In either case a hot iron should be applied to the gums, touching them lightly, not keeping it on. The cauterized gums should be anointed with honey and washed with mead. When the ulcers begin to be clean, drying medicaments are to be applied of the repressive kind.

"If, however, toothache appears and it is determined to remove the tooth because medicaments are of no avail, it should be shaved around so that the gum separates from it—then it is to be shaken. This is to be continued until it is easily moved, for to extract an adherent tooth is attended with great danger and sometimes the jaw is displaced. It is even more dangerous in the upper jaw because it may concuss the temples and eyes. Then the tooth is to be taken hold of by the hand if possible, if not, by the forceps (forfice) and if it is corroded, the cavity is previously to be filled with lint or well fitted lead so that it will not break under the forceps. The forceps must be drawn straight up lest, the root being inclined the fragile bone in which the tooth is fixed be broken, one side or the other; consequently danger is never absent in the operation at all events in the case of short teeth which have roots almost longer. For often where the forceps cannot seize the tooth or does seize it without effect, it seizes and breaks the bone of the gum. Where there is an excess of haemorrhage, one may know that something has been broken off the bone. Accordingly the shell should be examined with the probe (speculum) and drawn with the forceps (vulsella). If this is unsuccessful the gum should be incised until the loose shell of the bone is seized.

"If this is not done at once the jaw hardens externally, so that it is not possible to open the mouth. A hot cataplasm of flour and fig should be applied until pus is excited, then the gum should be incised.

"It is to be noted that pus flows profusely from a broken bone—so that even then it is proper to extract—sometimes indeed, from an injury of this kind a fistula makes its appearance which must be got rid of.

"A scabrous tooth of which part is black is to be scraped and anointed with roseleaves powdered to which a fourth part of gallnut and another of myrrh are added. Sour wine is to be held in the mouth frequently, the head is to be covered, much walking, exercise and friction of the head had, while acrid food is not to be used.

"If any teeth are loose from a blow or other accident, they are to be tied to others which hold fast, repressives are to be held in the mouth, such as wine in which pomegranate rind has been boiled or into which hot gallnuts have been thrown.

"If, again, in children one tooth grows out before that which should fall first, has disappeared, it should be drawn clean out: while the one which is produced in place of the former, should be pressed daily with the finger till it arrives at the proper size.

"Whenever the root is left after the tooth is drawn it should be extracted with that kind of forceps the Greeks call *rhizagra*" (that is the "Punch" formerly used for extracting roots of teeth).

About the last place one would expect to find any tooth remedies is a treatise on Vipers. But in the celebrated work of Marcus Aurelius Severinus, *Vipera Pythia . . . De Natura Veneno Medecina Demonstrationes et Experimenta Nova,* published at Padua, 1651, I read: "Conrad Tigurinus in his work on Serpents adds that the application of a viper's tooth elides toothache: also Pliny in Lib. 30, Cap. 5, alleges dentation to be promoted by vipers' teeth being attached to the infant. So Ponsettus believes pain in the teeth of adults to be relieved by tying the upper teeth of the enhydrus to the upper teeth of the patient, the lower to the lower. Moreover to scarify the aching teeth of men around with the largest tooth of the male white enhydrus will effect a cure," p. 359.

The word *enhydrus* is accurately *enhydris* literally transcribed from the Greek; Herodotus uses *enhydris* of the otter; lib. ii, 72; iv, 109: but others use the word of the watersnake. Pliny is the only classical Latin writer who has the word at all—he employs it for the watersnake.

In his *Naturalis Historia,* lib. XXX, 3, 8, he says: Moreover, for pains of the teeth some say the ashes of the heads without the flesh of dogs that have died of rabies is a sovereign remedy dropped with cyprus-oil into the ear on the side of the aching teeth. The largest, left tooth of a dog, the aching tooth being circumscribed; or the bone from the back of a dragon (*draco*) or of an *enhydris*—this is a male white serpent—they circumscarify with the largest tooth of this—they rinse the canine teeth with wine reduced to half its volume by boiling. The teeth are scarified with the bones of the lizard (lacerta) taken from its forehead in the full of the moon so that they do not touch the ground. . . . the ash of dogs applied with honey assists the slow dentition of children: a dentifrice is made in the same way. For hollow teeth the ash of mouse dung is inserted or the dried liver of lizards. If the heart of a snake is eaten or even applied it is considered effective. There are some who direct to eat a mouse twice a month and so avoid aches. Earthworms boiled in oil and dropped into the ear on the side of the toothache give relief—the ash of the same applied to corroded teeth makes them fall out easily; applied as an unguent it helps aching sound teeth—it should be burned in an earthenware vessel (testa). It is advantageous too to wash the teeth with a decoction of mulberry root in squill-vinegar. Then that little worm which is found in the plant called Venus' Lip inserted in the cavities of teeth is very helpful. . . . and bugs from the mallow are dropped into the ears with oil of roses. The fine sand which is found in snail-shells inserted in the cavities of teeth, stops the pain immediately. The ash of empty snailshells with myrrh helps the gums—the ash of a serpent burnt with salt in a jar along

*Read before the Academy of Dentistry, Toronto.

with oil of rose (is) dropped into the ear on the opposite side. The cast off skin of a snake heated with oil and pine-tar is dropped into either ear; some add frankincense and roseoil. This same preparation inserted in the cavities make the teeth come out without difficulty. I myself think it useless to speak of white snakes sloughing the membrane at the time of the rising of the Dog Star as that is not seen in Italy and it is much less credible that in warm regions this sloughing is delayed so late, and indeed the cast-off skin aged with wax they say draw the teeth quickly. And the tooth of snakes bound on mitigates the pain. There are some who believe that a spider caught with the left hand and ground with rose oil dropped into the ear on the same side is valuable." (The words I translate spider are *araneum animal ipsum;* they may mean the shrewmouse). . . .

"They say that the taste in the mouth is improved if the teeth are rubbed with mouseash mixed with honey; some mix the roots of fennel. If the teeth are scraped with a vulture feather, the breath is made sour—while to do the same with a porcupine quill tends to firmness. . . ."

Pliny in another passage, *Nat. Hist.,* lib. xxxii, c. 7, 26, says:

"Toothache is relieved by the gums being scarified with the bones of the seadragon: the decoction of the brain of a puppy (canicula) in oil and applied so that the teeth are washed with it once a year. Moreover to scarify the gums with the root of parsnip is very useful in toothache. That is triturated and anointed with white hellebore and it extracts the teeth without trouble. The ash of salt fish burned in an earthern vessel added to powdered marble is among the remedies; and old tunny fish burned in a new vessel, then triturated is excellent for toothache. They say that the backbones of all kinds of salt fish burned, triturated and unguented are equally beneficial—and frogs are to be boiled one in a half pint (*hemina*) of vinegar, the teeth washed with the fluid and the fluid kept in the mouth. If squeamishness is an obstacle, Sallustius Dionysius used to hang them up by the hind legs so that the virus would flow out of their mouths into hot vinegar—that he would do with many frogs—he gave frogs to those of stronger stomachs to eat with the broth. They believe that the maxillary teeth (the molars) are particularly healed in this way and loose ones made firm by the said vinegar. For that purpose some macerate the bodies of two frogs, the legs being cut off, in half pint of wine *dried,* the loose teeth to be washed with it. Others attach all of them to the maxillary —others again make a decoction of ten in three quarts of vinegar boiled down to a third, to stabilize the loose teeth. Then, too, the hearts of thirty-six frogs are decocted in a quart of oil under a potlid (i. e. in a covered pot) that this may be poured into the ear, for an aching jaw. Others apply to the teeth the liver of a frog, decocted and triturated with honey. All the above is more efficacious if marine frogs are used. If they are carious and fetid they throw a hundred of them into an oven to be dried during the night; then a sufficient quantity of salt is added and this is used for rubbing. The enhydris is a snake living in water and so called by the Greeks. They scarify the gums with four upper teeth of this snake in pains of the upper teeth, with the lower in pains of the lower—some are content with the canine tooth of them. They use, too, the ash of crabs; and the ash of mice is a dentifrice."

Sextus Plato, *De Cane,* ix, 24, says: "For toothache burn the tooth of a dog, decoct the ash in half a pint of wine, and gargle with it—a cure will be effected." In the same work, ix, 26, he says: "That the teeth may grow without pain, burn the tooth of a dog, triturate with honey and rub the gums firmly."

Habderrahmanus Aegyptius is said to have directed: "What is called the canine tooth of a dog appended to the neck of a child whose teeth have not yet appeared makes their eruption easy without any pain or injury." Delphin Ed. Plin. *Nat. Hist.,* vol. vii, p. 4080 note(d).

Quintus Serenus, c. 15, p. 314, says: "If by any chance you complain of corroded teeth burn mouse dung and put it into the gaping openings—the powder of earthworms roasted is also helpful." Marcellus Empiricus, Plinius Valerianus, Galen and others agree in this.

Marcus Aurelius Severinus was born in Calabria in 1580 and died at Naples in 1656—he was first a lawyer, then a medical man: he was fond of trepanning and the actual cautery and was one of the first to describe diphtheria. His fame was so great as a professor of medicine as to attract a large number of students to Naples—he was a daring and harsh operator.

"Finally and in conclusion"—the celebrated Franciscan Friar, mathematician and botanist of note, Louis Feuillée, in his sumptuous quarto published in Paris, 1725, *Journal des Observations Physiques, Mathematiques et Botaniques,* of what he saw in Chile and Peru, tells us of two plants used by the Natives dentally.

Chalo Origani folio. "The natives of this country (Chile) use this plant in severe toothache, washing the mouth with a decoction."

Geranium Columbinum perenne flore purpureo, Vulgo *Core-Core.*

"This plant is admirable for relieving pains of the teeth: the Indians have the root boiled in ordinary water and when they have toothache, they rinse the mouth with it and feel themselves relieved at once; it also has the property of hardening the gums; that is the reason that those of advanced age make great use of it.

I almost forgot our own Samuel Thomson, the founder of the last formal System of Medicine, the Thomsonian or Botanical School which had great vogue in the second quarter of the last century and is not quite dead yet, though I believe it no longer has a College. Thomson with all his fondness for Lobelia and Capsicum had his own share of good sound "horse sense" and if he did not cure many he saved many from being killed *secundum artem* by the Regulars.

For toothache, Thomson, or at least his followers (for the copy of his little book in my possession printed at Hamilton, Canada West, in 1833 is silent on the matter) advised to "chew the xanthoxylum or tooth bark: a piece the size of the finger nail is sufficient at a time. Repeat till the pain ceases —as effectual as anything of the stimulating kind or No. 6 put in the tooth." Thomson's No. 6 was about the same as Tr. Myrrh. Co. and contained Myrrh, Capsicum, and Alcohol, sometimes Camphor and Turpentine.

Contributors to the Science of Medicine

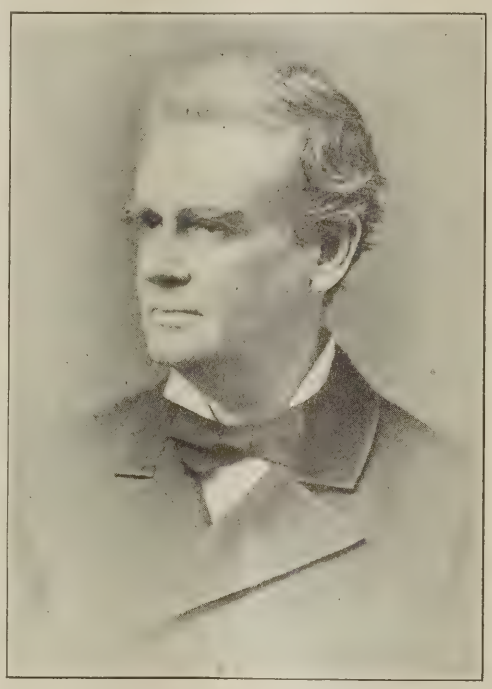
J. Marion Sims

J. Marion Sims was one of the very great, indeed the greatest of the pioneer surgeons of this country. He may be linked with William Beaumont and Ephraim McDowell, but he went further than either of these original investigators and surgeons, although it is only fair to say that he had greater opportunities.

James Marion Sims was born in Lancaster County, South Carolina, on January 25, 1813. His ancestors, on his father's side, were of the English colonists of Virginia, and on his mother's side he was of Scotch-Irish origin. They were all tillers of the soil. He graduated in arts from the College of South Carolina and studied medicine in the office of Dr. B. C. Jones at Lancaster, a small village in Lancaster County. He afterwards attended lectures at the medical college at Charlestown, South Carolina, but received his diploma from the Jefferson Medical Col-

lege of Philadelphia. When he had graduated he returned to Lancaster to practise, but meeting with little success remained there only a short time and removed to Mount Meigs, Alabama, where he remained about two years. In 1886 he returned to Lancaster to marry Eliza Theresa Jones. After his marriage he came back to Mount Meigs but left for Macon County in 1837 living near a small village, Cross Keys by name. Thence he came to Montgomery, a good sized town, with his wife and two children and settled there for several years. Here he had the opportunity of displaying his gift for surgery and operated largely for club foot and cross eyes.

He was a remarkably skilful surgeon and soon established his reputation as such and it was not long before he had one of the largest surgical practices in the state of Alabama. He was, moreover, greatly beloved and immensely popular. He was active in the formation of a medical society and performed almost all the important surgical operations known to the science of that day. One of the most important operations Dr. Sims did at this early stage of his career as a surgeon was that for cleft palate which he performed with extraordinary success and of which he wrote an account in the *Dental Journal*. At this time on the advice of a friend, Dr. Ames, he published accounts of all his chief surgical cases. When he had lived in Mortgomery for a year he maintained a private hospital in which to care for his surgical cases.



J. MARION SIMS, M.D

It was while he was in Montgomery, and after he had acquired a great local reputation as a surgeon, that he began to work out the vaginal speculum, by the invention of which his name is best known and which was first termed the duckbill speculum. However, before this he made what he thought was his first great discovery. He was called in to see an infant suffering from trismus narcentium, or lockjaw. Dr. Sims, after examining the baby carefully, concluded that the condition was due to mechanical pressure on the base of the brain, caused by the dislocation of the occipital bone brought about by the child lying on its back. The child died and a postmortem was made, from the outcome of which his view was confirmed at least to his own satisfaction.

Dr. Sims's doctrines in respect to the pathology and treatment of trismus nascentium were not accepted generally. In January, 1884, Dr. J. F. Hartigan, of Washington, published an article in the *American Journal of the Medical Sciences,* entitled Trismus Nascentium; Its History, Cause, Prevention and Cure. The article contained the report of two hundred and twenty-nine cases and with regard to diagnosis set forth the theory of causation which the author found had been advanced over thirty years before by Dr. J. Marion Sims, then of Alabama.

It was shortly after this that he made uterine surgery his special study, and restricted his hospital solely to females and to such cases in uterine surgery as were best calculated to test the value of the aforementioned speculum. His interest was first aroused in vesicovaginal fistula by a case he attended. Soon after he was called in two similar cases and he became so intensely concerned with the question of treatment of all uterine disorders and vesicovaginal fistulæ in particular, that he induced his medical friends to hunt up for him difficult cases of uterine disease, which had resisted treatment, and especially of that loathsome condition, vesicovaginal fistula, which had ever been the stumbling block of surgery.

The district in which he lived provided many opportunities for investigating uterine disorders as they abounded among the negro population. Alabama was a slave state, and the negro women were attended usually in their confinements by ignorant midwives of their own color. His efforts were encouraging from the outset and he pursued his path undeterred by difficulties or failures. He intended to reach his goal if indomitable will and unfailing perseverance would get him there. He worked on and on, sometimes performing dozens of operations on the same patient until at last his end was gained. In Dr. Sims's autobiography a chapter is given up to the tale of his experimental operations and of his final success with the speculum.

During all this time he was thinking out methods and plans of procedure for his operations, and at the same time was inventing instruments and appliances as aids to his speculum. All this happened between 1845 and 1849 and although his life had been strenuous, yet from the consciousness that he had greatly succeeded in his ambition to save women from suffering added to the fact that he was prosperous and that his domestic life was ideal he was contented and happy.

The first blow that came was the death of his second son, and then six weeks after his success with vesicovaginal fistula he collapsed and for some time he traveled from resort to resort in the endeavor to regain health. In 1851 Dr. Sims, who was convinced that the climate of Alabama did not suit him, bought a house at 89 Madison Avenue, New York, and for a considerable time made little or no headway. Then the idea struck him of establishing a woman's hospital and after encountering almost incredible difficulties succeeded in doing so. This is the description the founder gave of it in his autobiography: "The Woman's Hospital from the day it was opened had no friends among the leading hospital men. I was called a quack and a humbug, and the hospital

pronounced a fraud. Still it went on with its work. Its wards were open to any doctor that cared to come, and the operations performed there were seen by most of the leading men of the city, and by many others from different parts of the country."

Finally funds for a new building were raised and the woman's hospital was built in exactly the way that its founder desired. As said before, the hospital was established under quite extraordinary difficulties and opposition, as is so frequently the case when prejudice and tradition conflicts with new views. This success in overcoming the hostility, jealousy and pettiness of others was a great tribute to his powers of magnetism and to his untiring energy.

In 1861 he paid his first visit to Europe; he landed at Queenstown and went to Dublin where he had a warm welcome from his Irish brethren. He then journeyed by way of Belfast to Edinburgh where he was received with enthusiasm by Simpson, Syme, Christison and Matthews Duncan. Of this galaxy of talent Sims was most greatly impressed by Syme. Although he had seen all the great surgeons operate in America, in London and Paris he had never seen such an operator as Syme. In London, Sims was received as cordially as elsewhere, and he was called upon immediately to operate on a case of vesicovaginal fistula at the Samaritan Hospital. He arrived in Paris in the fall of 1861 and was invited to operate in a case of vesicovaginal fistula, and despite the fact that the case was a bad one and that the operation was performed under extremely unfavorable conditions, it was completely successful. After doing the same operation in several Paris hospitals at the request of the King of Belgium, Sims performed three operations in Brussels. He had an immense success in Paris, and in connection with an operation he did there in which the patient nearly died from chloroform narcosis he delivered himself of some very apt comments on the relative value of chloroform and ether. He said, "Chloroform is delicious and dangerous; ether is disagreeable and safe in purely surgical cases."

When he returned to America in December, 1861, his countrymen were in the midst of the Civil War, and he returned with his family to Paris in the midsummer of 1862, where he found that the work he had done there in the previous summer had given him such a reputation that he had no trouble whatever in making a good income. Among other things, he became physician to the Duchess of Hamilton and in 1863 went with her to Baden-Baden to spend the summer. While there he wrote a book entitled *Clinical Notes on Uterine Surgery*. In his own words, "It was so radical and revolutionary in all the methods adopted that the profession did not at first readily accept its teachings, but in a few years it completely revolutionized the subject of gynecology" and he went on to say, "Before that time there was not a professorship of gynecology, worthy of the name, connected with any of our medical schools, and now we have professorships of this department in every medical school in the country, and, indeed, throughout the civilized world." In his memoir of Dr. Sims, the well known surgeon, Dr. Thomas Addis Emmet, says of the book, "Its publication was the turning point of modern gynecology, or, more strictly speaking, American gynecology, of which he may be justly termed the father."

In 1863 the Emperor of the French, Napoleon III, sent for Dr. Sims to consult him as to the health of the Empress, and for a few weeks he had professional supervision of her health. After 1863 Dr. Sims was resident in London for a time. In 1870, while in Paris, he aided in organizing the Anglo-American Ambulance Corps, for service in the French army in the field during the Franco-Prussian War. He was surgeon in chief of the corps, with a staff of seven American and eight English surgeons. He arrived on the field of Sedan just before the battle. Dr. Sims remained at Sedan a little over a month, when he resigned his position returning to this country in January, 1872. He was appointed a member of the Board of Surgeons of the Woman's Hospital and resigned in December, 1874, owing to differences with the board of management. The American Medical Association elected him its president in 1876. After a visit to the South and the place of his birth, he returned to New York and in the fall of 1877 went back with his family to Paris. He was made president of the American Gynecological Society in 1880. Dr. Sims's health was never robust, and yet in spite of his delicate physique he had remarkable vital powers and was capable of prolonged physical exertion. While in New York in the winter of 1881, he was attacked with pneumonia which nearly proved fatal. In speaking of it he was wont to say, "But for that attack of pneumonia I would probably have lived to the age of ninety."

Early in 1882 he again went to Europe and remained in Paris until August, 1883, when he returned to New York. In October he bought a plot for a house in Washington, the title deeds of which were executed but three days before his death. He had intended to sail for Southern Europe on November 8th, to escape the American winter, but was persuaded by his friends to defer his departure until the seventeenth of that month in order to perform a delicate and difficult operation on the wife of a prominent citizen of New York. On the night of November 12th, returning from a visit to this patient, he caught a chill and died on November 13th.

The fame of Marion Sims rests upon his treatment and cure of vesicovaginal fistula and upon his improvements in the treatment of uterine disorders generally. He revolutionized gynecology. His name will be carried down the ages as the inventor of the speculum which bears his name.

In the words of his friend, Dr. W. O. Baldwin, "Gynecology today would not deserve the name of a separate and cultivated science, but for the light which Sims's speculum and the principles involved in it have thrown upon it. It has been to diseases of the womb what the printing press is to civilization, what the compass is to the mariner, what steam is to navigation, what the telescope is to astronomy, and grander than the telescope because it was the work of one man. Those great philosophers Galileo, Gregory, Herschel and Newton, all claim and deserve the honor for successive parts of the telescope. Sims alone discovered and invented the speculum and like Minerva from the brain of Jupiter, it sprang from his hands alone, full fledged and perfect when he gave it to the world."

Editorial Articles

INSANITY AND CRIME

The most glaring feature of human life is the vast amount of mental disease and its concomitant, crime. What is out of sight is out of mind and because criminals and the insane are isolated to a large degree we forget their hideous number, and because our tax bills are not itemized we do not realize the heavy burden these unfortunates place upon their fellows. Between international insanity, war, and individual mental derangement we are well nigh bankrupt. There seems to be little sign of improvement, and, while much is being done by private agencies wtih a view to getting at fundamental causes, this is not half enough.

The public suffers from mental disease more than the individual, and the public should finance and further the best of research in this direction. We have governmental bureaus for the study of diseases of plants and of animals, also the diseases of man that are of physical origin, but there is no adequate means of getting at the etiology and prophylaxis of crime and insanity.

These are days of economy in government activities, and many bureaus are sorely pinched for funds, but there is no economy in not trying to do away with the enormous wasters of our public resources. Mental health is purchasable to a degree, and there is nothing finer for which we can spend our cash, while the financial return on so wise an investment should be most extraordinary.

THE NEW SURGERY

Electrosurgery has made very considerable progress since the method was first instituted. Nagelschmidt, if he was not the originator of surgical diathermy was, at any rate, one of the earliest pioneers. He had practised diathermy for some time when he was invited in 1910 to give a demonstration of surgical diathermy at St. Bartholomew's Hospital in London. He there treated three surgical cases.

Dr. Albert Tyler, of Omaha, was one of the first in this country to use the method and has confined treatment principally to diseases of the face and mouth and says he has treated cases of malignant tumor successfully. One of the first exponents of surgical diathermy is Gustav Kolischer, of Chicago, who has treated many cases of malignant tumor with satisfactory results by electrocoagulation.

Mr. J. E. McDonagh is one of the chief advocates of this theory of disease and its treatment, expressing these opinions in *The Nature of Disease* published some months ago. However, by no means all those surgeons who practise electrosurgery believe this theory, but they do believe in the efficacy of such treatment in suitable cases. At the meeting of the American Academy of Physiotherapy held in Atlantic City, May 25 and 26, 1925, Howard A. Kelly, of Baltimore, read a paper on the new surgery, and William D. Mcfee, of Boston, one on electrocoagulation in surgery. These papers were published in this JOURNAL on July 1st. Kelly, who has had much experience with the new surgery, namely, bipolar electrocoagulation and monopolar desiccation of William A. Clark and electric cutting needle of George A. Wyeth. Kelly first describes the acusector, the needle functioning as a knife and actually separating tissues as neatly and readily as a scalpel. He describes the technic of the various operations for which the acusector can be employed, and points out where care must be taken in its use.

The advantages of bloodless surgery are summarized as follows: There is at the disposal of surgeons a set of new agents destined to remodel surgical technic over a large field. 1. The new electric methods are not simple substitutes or alternative methods of doing what we have done equally well by other procedures. 2. These methods are not to be learned completely in a week or a year. They call for careful attention to a new technic, for discriminating judgment in their application, and for increasing boldness with a growing experience. The concept is new. 3. They will succeed often where surgery and radium have failed, although they do not exclude or wholly supplant either. 4. In operating by these new methods the motto might well be stated as "hands off," as there is so little fingering of the tissues. 5. Not least of the advantages of the new procedures are those of lessening hemorrhage, a more rapid disposal of diseased and infected tissues and a considerable shortening of the duration of the operation. 6. A larger percentage of the cases can be treated as ambulatory, after having been treated under local or short gas anesthesia. 7. Pain is lessened, owing to the destruction of the sensory nerves. 8. Healing is better.

There is no doubt, however, that if, as Kelly says, the allegations in his paper are true they fully justify the title "new surgery." It is to be hoped that further experience will substantiate his claims and until that time arrives it will be well to retain an open mind. It must not be forgotten that the well known Balti-

more surgeon acknowledges that both skill, judgment and experience are necessary to manipulate the acusector with safety and that therefore the new concept must be thoroughly studied and understood and a technic mastered before a surgeon undertakes a bloodless operation.

THE RELATIONSHIP OF ACIDOSIS AND ACETONEMIA TO SEASICKNESS

While the basic cause of seasickness may be largely psychological there are other and physical reasons which enter into its causation. For example, if a person suffers from gastrointestinal troubles it would seem reasonable to assume that such persons are more apt to be victims of *mal de mer* than those whose organs of digestion, assimilation and excretion are in good working order. Moreover, some people appear to have a certain idiosyncrasy to severe gastric disturbances when on the ocean. In the *British Medical Journal,* January 17, 1925, Dr. B. Sidney Jones, Surgeon R. M. S. *Aquitania,* has an interesting and suggestive communication with regard to seasickness. Dr. Jones has been going to sea off and on for thirty-one years but it is only comparatively recently that he has associated acidosis and acetonemia with seasickness.

The incidents which drew his attention to this possibility were the extraordinary number of cases in women in the middle or late stage of pregnancy, who, having ceased vomiting in the early months, commenced to vomit again after coming aboard, and some cases of intractable vomiting in children, when the movements of the ship were so slight as to be out of all proportion to the degree of sickness. It may be said that the children often had a previous history of cyclical vomiting. Dr. Jones's investigations during three years showed increased acid and acetone in the urine in almost all cases of apparent seasickness. In short, he has come to the conclusion that, although seasickness may not be due to these causes, the presence of acidosis and acetonemia in such a very large proportion of cases seems more than a coincidence and worthy of investigation.

Starvation is not the cause of the acetone present as some people vomit shortly after the ship sails, or even as soon as they set foot on deck. The author thinks that the sympathetic system may act on one or more of the endocrine glands, possibly the pancreas, and thus cause the fats to be broken up into these substances instead of into carbon dioxide and water, as is known to happen in diabetes.

What tends to add weight to the belief that there is a fairly close relationship between acidosis and acetonemia and seasickness is the fact that these cases, especially in children, respond very readily to alkaline treatment. Consequently, Dr. Jones concludes, investigations have shown in his practice that more than ninety-nine per cent. of cases of vomiting at sea, not due to an obvious organic lesion, have been accompanied by increased acidity and acetonemia; that the sickness clears up quickly under an intensive antacid treatment, and that it would therefore seem to follow that it is advisable to have any hyperacidity corrected before embarking.

If the investigations of the medical officer of the *Aquitania* are confirmed by further experience then seasickness can be prevented or quickly aborted.

A NEW AID IN THE DIAGNOSIS OF BRONCHOPULMONARY LESIONS INCLUDING TUBERCULOSIS

Much difficulty has been experienced in diagnosing correctly certain bronchial and pulmonary lesions. The bronchoscope has been of great aid in this direction and its potentialities and possibilities are by no means ended. In fact, the field of bronchoscopy is constantly widening. The last use to which the bronchoscope has been put is to inject lipiodol for diagnostic purposes.

Lipiodol, a preparation of iodine, is a French pharmaceutical product. Although only introduced in radiology during the past two or three years it appears already to have been a striking success and has been employed in the Royal Victoria Hospital, Montreal, to diagnose lung conditions which could not have been diagnosed satisfactorily by any other known means.

At the meeting of the New York Central Railway Surgeons, held in Montreal on October 20th and 21st, Dr. Edward Archibald, professor of surgery at McGill University, demonstrated at a clinic of the Royal Victoria Hospital on October 20th, before surgeons of this association, the diagnostic value of lipiodol. He pointed out that the object of the clinic was to lay stress on the value of this product in showing up cavities and bronchiectasis in tuberculous lungs. The histories of patients were given, on whom from two to three years previously the operation of total posterior thoracoplasty had been performed. After improvement, extending over varying periods, symptoms characterized by cough and increased sputum had recurred. The operation of thoracoplasty involving extensive rib removal, the reforming of bone, irregular outline, together with the usual considerable thickening of the pleura, is to render diagnosis of the existing condition by ordinary methods impossible. The x ray plate is so obscured that no detail of lung structure can be detected, nor is any aid to be had from physical examination, owing to the condition of the lung and the thickness of the tissue generally.

In the circumstances resort was had to injection of lipoidol by the bronchoscope. This was done by Dr. David H. Ballou, of the otolaryngological department of the Royal Victoria Hospital, who in an article in the *Canadian Medical Association Journal* describes the procedure of injection. A remarkable feature of lipoidol is that although it is a preparation of iodine it is nonirritating. As Dr. Ballou says, that it has no irritating effect is evidenced by the fact that in spite of its presence in the lung for a considerable time, as demonstrated by x rays, it produces scarcely any cough in the normal person.

Dr. Archibald and those colleagues with whom he has been experimenting with lipoidol as a diagnostic agent in obscure lung conditions are enthusiastic as to its future.

THE RELATIONSHIP OF THE MINERAL ELEMENTS OF THE BODY TO DISEASE

Evidence of the essential need for the mineral salts in the body in their proper proportions is accumulating almost every day. Of these mineral elements most is known of iodine and calcium and it is now a matter of common knowledge that if these be lacking ill health will follow.

Iodine has come to the front recently as one of the most necessary constituents of the human organism, and its deficiency as one of the most common causes of disease.

There exists more or less precise knowledge concerning the thyroid gland. It is probably the director of the endocrine system and if it fails to perform this office efficiently, the entire system suffers. Also, the smooth working of the thyroid is dependent upon its iodine content, and if this is lacking, the thyroid is unable to do those services which are essential to good health. A condition of low resistance of the tissues to disease ensues, and the system is prone to be attacked by any of a long list of diseases, many of which if not prevented from developing will assume the chronic form. Swelled glands and tonsils, little or no appetite, pallor, and listlessness are some of the symptoms which characterize a deficiency of iodine in the system in children. Simple and other forms of goitre in adolescents and adults, while in middle age rheumatism in its chronic form is perhaps the chief distinguishing marks of iodine privation.

The most sinister feature of a paucity of iodine and calcium in the system is that such a deficiency renders the subject, and the young in particular, susceptible to the infectious diseases. It is believed, and the evidence seems strong, that heart disease in children, which generally becomes permanent, is contracted frequently as the result of acute rheumatism or of another infectious disease and these infections only attack children who are peculiarly open to invasion by microbic toxins because of a deficiency of iodine in the thyroid gland. Again, in tuberculosis there is usually a negative calcium balance and it appears reasonable to presume that resistance to tuberculosis is diminished by an insufficient supply of calcium in the body.

In tuberculosis, anemia, dyspepsia, neurasthenia, rickets, dental caries, in pregnant women and in several chronic diseases there is an excessive excretion of calcium or demineralization. In nervous diseases there is a large loss of calcium. Deficiency of calcium is likely to occur in an adult urban population and, in inland districts in particular, deficiency of iodine is a common cause of malnutrition in children and of simple goitre in adolescents and adults. In many parts of this country the fact that endemic goitre is largely due to lack of iodine is fully recognized.

But there is another point to be considered in connection with this subject and that is, how is it that the iodine content of the thyroid becomes lessened and the calcium content of the body excreted too profusely. So far as the iodine supply of the thyroid is concerned, a mass of evidence goes to show that intestinal toxemia is frequently the cause of the impaired functions of the thyroid.

SURGEONS OF THE STONE AGE

Among the distinguished foreign guests at the recent meeting of the American College of Surgeons in Philadelphia none was more worthy of honor than the Italian surgeon, Vittorio Putti, who in the field of arthroplastic surgery hardly knows a rival. Dr. Putti is a professor in the ancient and famous medical school of the University of Bologna, one of those Italian universities which kept the torch of medical and surgical learning burning at a time when in the rest of the world it was dead or dying.

Dr. Putti took occasion, while in Philadelphia, to point out that the men of today are slow to realize how much was known of medicine and surgery in past ages. For example, men of the stone age, that age before records of history were kept, knew how to trephine, in a rough way no doubt, but it seems that they did know how to relieve pressure on the brain by this method.

Dr. Putti went on to draw attention to the fact that there was medical teaching at Salerno as early as the ninth century. The knowledge of surgery was taken to Italy by Greek surgeons and developed by Benedictine monks. Those surgeons of a thousand years ago knew how to perform amputations, knew how to deal with fractures, and knew of many opera-

tions for relief of diseased conditions. However, since aseptic surgery had not yet come into existence, abdominal operations such as are common today were little attempted.

As for anesthesia, it was known and used centuries ago. Ether and chloroform as anesthetics are modern discoveries, but opium had been known and used as an anesthetic for hundreds of years.

Obituary.

EDWARD BENNETT BRONSON, M.D.

New York

The tragic death by fire, on November 18th, of Dr. Edward Bennett Bronson came as a great shock to his friends and colleagues in New York City. Dr. Bronson was born in Hartford, Connecticut, on June 12, 1843. He was graduated from Yale University in 1865 and took his degree in medicine at Columbia University, New York City. His line of special interest in medical science was dermatology, and he was an active member of the New York Dermatological Society and of the American Dermatological Association. He was also widely known as an able consulting physician, and at the time of his death filled this position at the New York City Hospital and at the New York Babies' Hospital. He was a Fellow of the New York Academy of Medicine, and a member of the American Medical Association. He belonged also to the New York University Club, of which he was at one time president, and to the Century Club and the Quill Club.

Dr. Bronson had always retained, in spite of his advanced years, a keen interest in his profession and prided himself in keeping up to date in his medical knowledge and in his interest in life as a whole. He had a wide and devoted circle of friends, both professional and otherwise, to whom his death comes as a heartfelt loss.

WILLIAM EMERY STUDDIFORD, M.D.

New York

Dr. William Emery Studdiford, one of the best known surgeons in this country, died on November 17th in his fifty-ninth year at his home in New York. Soon after Dr. Studdiford's return in the fall from a European trip, he suffered a heart attack, which, however, was not regarded as serious, so he continued his practice as before. A few days before his death he suffered another attack while operating at Sloane Hospital for Women, and was hurried to his home. Even then his condition was not deemed serious, so his death came as a shock.

Dr. Studdiford was born in Trenton, New Jersey, on July 4, 1867. His father was the Rev. Samuel Studdiford, who was for nearly fifty years pastor of a Presbyterian church in Trenton. The son, William, was graduated from Princeton University in 1888, and in 1891 took his master's degree at the same institution. In the same year he received his medical degree from Bellevue Medical College. After an internship at Bellevue, Dr. Studdiford became the assistant of the late Dr. William P. Lusk, and after a few years, was made assistant attending physician at Bellevue. In 1914 he became attending physician on the staff of the late Dr. E. B. Cragin, and in the same year was made professor of gynecology and obstetrics at New York University. In 1919 he succeeded Dr. Cragin as professor of gynecology and obstetrics at the College of Physicians and Surgeons, Columbia University, and as director of Sloane Hospital. During the latter years of his life he held the position of consulting gynecologist at the Presbyterian Hospital, New York City.

Dr. Studdiford was active in his work until the very end of his life, as the fact that he was stricken while operating testifies. He was a man of unusual strength of character, the broadest human sympathies, and of great personal charm, so his circle of friends was a very wide one. His work was known not only in his own land but was also recognized abroad. He was indeed a master surgeon.

GEORGE W. CRARY, M.D.

New York

The death of Dr. George W. Crary, well known dermatologist, at his Park Avenue home, New York, on November 16th, came as a great shock to his wide circle of friends. Dr. Crary was born in Brooklyn on January 3, 1864. He was graduated from the Brooklyn Polytechnic Institute in 1881 and from the Medical Department of Columbia University in 1885.

His first professional position was that of house surgeon in Bellevue Hospital. Later he was made assistant demonstrator in anatomy at Columbia and assistant attending surgeon at Roosevelt Hospital and was gaining recognition in these fields when he was stricken with paralysis after an attack of pneumonia, which deprived him of the use of one of his arms. By no means discouraged by this apparent serious setback to his work, Dr. Crary went to Europe and spent three years studying dermatology in the hospitals of Berlin and Vienna, and upon his return to this country was made attending dermatologist at Cornell Medical College. He was consulting dermatologist at the New York Lying-in Hospital from 1903-1905, and had been consulting dermatologist at the General Memorial Hospital since 1903; at the Lincoln Hospital since 1907, and at the New York Infant Asylum since 1908.

Dr. Crary was a member of the Manhattan Dermatological Society, a fellow of the New York Academy of Medicine, a member of the Medical Association of the County of New York, the Medical Association of Greater New York, the Society of Social and Moral Prophylaxis, the Physicans' Mutual Aid Society, the American Forestry Association, the New York Forestry Association, the Metropolitan Museum of Art, and other organizations, the character of his memberships and the active work which he contributed to all testifying to the breadth and inclusiveness of his many interests. He was extremely fond of outdoor life and camping, and was an authority on nature study and biology, as well as medical science.

The Vichy Mineral Springs

CHARLES GREENE CUMSTON, M.D.

Geneva, Switzerland

For more than a quarter of a century I have sent patients suffering from stomach and liver disorders to Vichy, and the results obtained by treatment with these waters have, on the whole, been extremely satisfactory. Consequently, when I myself became the subject of diabetes, it was only natural that I should take a cure there, which I did this summer.

The indications for cures at this resort may be conveniently tabulated as follows:

GASTRIC AFFECTIONS

Primary types.—Hyperpepsia; intermittent hyperchlorhydria; hypopepsia; apepsia and neuromotility disturbances of the stomach.

Secondary types.—Arthritic and toxic (gastrohepatic) dyspepsias; dyspepsia dependent upon enteroptosis.

LIVER AFFECTIONS

All types of hepatic congestive processes and biliary lithiasis. The congestive phase of cirrhosis—before the cachectic phase is reached—is also an indication for a cure.

TROPICAL DISEASES

From personal experience I am convinced that the waters of Vichy are absolutely indicated in malaria and other tropical diseases involving the hepatic gland, the diabetes of obese subjects, arthritic obesity, uricemia and certain forms of gout.

Reference will not be made here to the medicinal uses of each of the several springs at Vichy as this subject is within the realm of the specialist, which I am not. What is to follow is based on my personal experience.

ACTION OF WATERS ON DIGESTIVE TRACT

First, in reference to gastric processes it is to be remarked that Vichy, like all other similar spas, is not indicated in all stomach diseases. In cases of gastric or duodenal ulcer in the active stage the patients must never be sent there, while it is questionable whether or not hyperchlorhydria is benefited. For all other gastric lesions are unquestionably relieved by these waters. The therapeutic effects of the waters are due to factors other than chemical and in a short time the stomach is brought into a state of rest, digestion is accelerated, fermentation neutralized and pain and nausea alleviated. The waters are easily assimilated with the result that all tissues and secretions are stimulated, the gastric glandular system tend to become normal, hence the secretion of the gastric juices is promoted.

Arthritic dyspepsia dependent upon an excess of urea and uric acid in the urine, and the toxic dyspepsias resulting from overeating and too free indulgence in alcohol, are especially influenced by the waters.

CHOLAGOGUE PROPERTY OF WATERS

Coming now to hepatic affections, let it first be said that Vichy waters have a very potent action on the secretion of bile. This cholagogue property is due to alkalization of the entire economy by their use, thus increasing the fluidity of the bile. The hepatic cell metabolism is stimulated, hence toxic matter is either

FIG. 1.—Massage under hot water spray.

FIG. 2.—Massaging hot water douche under water.

eliminated or destroyed. It is hardly necessary to say that in order to obtain really good effects, patients should be sent before the physiological integrity of the hepatic cell has been destroyed by the morbid process, otherwise—as with any other therapeutic measures—no good will result.

From my own clinical experience I have been able unhesitatingly to say that in chronic cholecystitis, the diabetes of fat subjects (arthritics), hepatic congestion, the result of overfeeding or the overindulgence in alcoholic drinks, and in the early phases of cirrhosis, the cures at Vichy are unsurpassed by any other spa on the continent. I am likewise inclined to suspect that in certain forms of biliary lithiasis the patients may derive benefit at this spa, and I have frequently ordered cures at Vichy in postoperative cases of gallstones and various forms of surgical cholecystitis with clearly excellent results.

Dr. G. Monod, of Vichy, informed me that if the nature of the treatment carried out there was better understood by the profession at large, uricemic patients and those suffering from various forms of gout would be sent there, much to their advantage.

Every type of bath and percussion douche is to be found in Vichy and everyone knows the therapeutic value of the douche in all its various forms. Reference is especially to be made of massage under water by means of a hot douche (from 36° to 40° C.) which is directed over the epigastric region for ten or twelve minutes—a most delightful therapeutic procedure, which I can vouch for from personal experience. The force of the douche gives a soft massage which is very efficient and not fatiguing to the patient (Fig. 1).

Another form of massage under water is depicted in Fig. 2.

MECHANOTHERAPY

Mechanotherapy is now recognized as an important adjunct to hydrotherapeutic cures and is extensively carried out. Fig. 3 gives an excellent idea of the fine plant at Vichy.

DIVERSION

One other important feature of Vichy is its beautiful parks where under their magnificent trees one can be refreshed in warm weather. It is never excessively hot there, the maximum heat in July and August varying from 80° to 84° F. And to make one's stay still more pleasant, there is a fine opera house where all that is best in music may be heard nightly in the form of opera or symphony concerts with the concourse of the best artists in Europe. There are several other theatres and music halls where mental diversion of a lighter kind may be obtained, and are not to be despised, because many patients are mentally depressed and amusement is often essential in medical treatment.

The mineral waters of Vichy were well known in the time of the Romans. They afterwards lost their celebrity and did not regain it till the seventeenth century, in the latter half of which they were visited and written of by Madame De Sevigné. At the present time Vichy is one of the best known and perhaps the most frequented watering place in France.

FIG. 3.—The Vichy Institute of Mechanotherapy.

INTERNATIONAL ASSOCIATION OF UNIVERSITY TEACHERS OF MEDICAL ROENTGENOLOGY

A survey of the development of medical science during the World War in the most prominent countries has given some very astonishing results. The astonishment was especially marked in the more recent röntgenology, the second developmental period of which occurred during this time of the complete separation of the ways. The paths it has followed have led to widely divergent directions—much further than merely indifferent variations of opinion. As a result, there have developed the most contradictory views and measures and it is conceivable that there should arise within the circle of this specialty the desire to know, in the first place, the stage of advancement of röntgenology in the different countries, and then to inaugurate an exchange of experiences and ideas on questions of investigation and study.

For this purpose a loose International Association of University Teachers of Röntgenology, consisting of a moderate number of suitable members, seems proper. Such a proposal, originated by a Viennese committee of the undersigned, found growing favor. Numerous replies to circulars have been received and valuable material contributed up to the present time by sixty-one academic teachers of röntgenology, or of this branch and a clinical specialty, make possible a preliminary survey. These sixty-one ordinary members include:

Professors in ordinary of medical röntgenology	11
Professors in ordinary of medical röntgenology and electrotherapy and physiotherapy, respectively	6
Professors in extraordinary of medical röntgenology and clinical medicine and surgery, respectively	3
Associates in medical röntgenology	17
Associates in medical röntgenology and clinical medicine or surgery	2
Associates in röntgenology and radiology	3
Associates in medical röntgenology and electrotherapy, and possibly physiotherapy	6
Lecturer in medical röntgenology	1
Total	61

University instruction in this specialty has advanced to different stages, as is shown by the following table, which includes only those countries from which complete information is available:

	I	*II*	*III*
Countries	*No. University Lectures on only (pure) Medical Radiology*	*No. Medical Faculties or Medical Schools*	*Proportion (in each school)*
Germany	5	23	0.2 (5:23)
Jugoslavia ..	1	2	0.5 (1:2)
Austria	12	3	4.0 (12:3)
Roumania ...	1	3	0.3 (1:3)
Russia	12	12	1.0 (2:3)
Switzerland .	2	3	1.7 (2:3)
Czechoslovakia	4	3	1.3 (4:3)
Hungary ...	2	4	0.5 (2:4)

Italy, the United States, and other countries show especially high figures, but the complete material has not as yet been furnished to the association. The differences in the general interest in this specialty are slight, but everywhere, as with us, it is extraordinarily marked and beyond all expectations.

Those teachers of röntgenology who have not been reached by our call or who have not as yet joined us, we herewith invite to suitable cooperation. This association will also include numerous advisory members.

With this short report and with the detailed proceedings to be published in the *Fortschritten auf dem Gebiete der Röntgenstrahlen,* as well as in the röntgenographic archives of all languages (membership list, etc.), the association hopes to render assistance by the extension of the present state of the specialty, to approach its aims, and thereby to cooperate toward the reunion of minds, which is one of the purposes of this association.

The Directing Committee,
Haudek, Holzknecht, Kienböck, Weber.

News Items.

Harvey Lecture.—Dr. Warren H. Lewis, professor of physiological anatomy, Johns Hopkins Medical School, will deliver the third Harvey Society Lecture at the New York Academy of Medicine, on Saturday evening, December 12th, 1925, at eight-thirty. His subject will be On the Origin of Macrophages and Epithelioid Cells, from Mononuclear Blood Cells.

Food and Health Exhibit.—The first exposition to be held in the new Madison Square Garden will be the third annual Health and Food Exposition, opening December 14th. The New York City Health Department will demonstrate the method of keeping the city's supply of oysters pure, and it is sponsoring an exhibit of the latest surgical, medical and sanitary equipment of the city's hospitals, which will be explained to the public by nurses and physicians.

Phonograph Records of Heart Murmurs.—An agreement has been made between Dr. Richard C. Cabot, of Harvard University Medical School, the Columbia Phonograph Company, and the Bell Telephone Company, whereby a set of phonograph records will be prepared, showing the murmurs characteristic in all heart lesions. An electrical stethoscope developed by the Bell Telephone Company eliminates by means of a series of electrical filters the heavy sounds of the heart beats which mask the more delicate murmurs upon which diagnosis depends.

United Hospital Fund.—This organization is conducting a campaign to raise one million dollars for charity work the coming year in the fifty-seven hospitals which are its members. The Fund reports a total number of 3,342,500 days of hospital treatment given during the last year, of which 1,563,650 days were free. In addition to hospital care, a total of 720,000 persons were treated in the clinics and dispensaries of the group, and 42,000 ambulance calls were made. To meet this cost, contributions were received from the public amounting to $544,859, and the endowment fund was brought up to $551,675.

Personal.—Dr. George H. Bigelow has been appointed commissioner of public health of Pennsylvania; he was formerly director of the Cornell University Medical College Clinic, of New York.

Dr. Archibald Malloch, of Montreal, has been appointed librarian of the New York Academy of Medicine. Doctor Malloch is a nephew of Sir William Osler, and worked with him for many years.

Dr. Donald C. Smelzer, of the Buffalo General Hospital, Buffalo, New York; has resigned to become superintendent of the Charles T. Miller Hospital, of St. Paul, Minn.

Dr. Solomon Solis-Cohen, of Philadelphia, has been elected a member of the board of education.

Dr. Walter Taylor Dannreuther, of New York, was given a testimonial dinner at the Ritz-Carlton Hotel, in recognition of his appointment as professor of gynecology at the New York Postgraduate Medical School and Hospital.

Dr. Adolf Gundersen, of LaCrosse, Wis., one of the regents of the state university, has been honored with the Knighthood of St. Olaf, by the King of Norway.

Dr. John W. Leckie, formerly of Hazelton, Pennsylvania, is the new medical director of the West Mountain Sanatorium at Scranton.

Midwinter Session of the American Electrotherapeutic Association.—A Midwinter Session of the American Electrotherapeutic Association will be held on January 6th and 7th, 1926, at the New York Academy of Medicine, with the cooperation of the New York and Philadelphia Electrotherapeutic Societies and the New England Association for Physical Therapeutics, and will be followed on Friday, January 8th, by a day of clinical demonstration at the Reconstruction and Beekman Street Hospitals. All legally licensed physicians are invited to attend and programs can be obtained by addressing the secretary, Dr. Richard Kovacs, 223 East 68th Street, New York City.

Baltimore Medical Club of New York City.—This club, the membership of which is made up of physicians graduated from Johns Hopkins University, and other medical colleges of Baltimore, but who are practising in New York City and vicinity, will hold its semiannual dinner at the Waldorf-Astoria, on Saturday evening, December 5th. Dr. Lewellyn F. Parker, of Johns Hopkins University, will be the principal speaker. The officers of the club are Dr. James M. Hitzrot, president, Dr. David E. Hoag, vice-president, Dr. Leslie T. Gager, secretary, Dr. W. B. Pritchard, chairman of the executive committee, and Dr. L. Winfield Kohn, chairman of the entertainment committee. Graduates of any of the medical colleges of Baltimore are eligible. Tickets may be obtained from Dr. Leslie T. Gager, 128 East Sixtieth Street.

Society News and Notes.

The Medical Society of the County of New York held its annual meeting on November 23d at the Academy of Medicine. There were addresses by Dr. Wendell C. Phillips, president elect of the American Medical Association, and Dr. Nathan B. Van Etten, president of the Medical Society of the State of New York. The anniversary address was made by Rev. Cornelius Woelfkin.

* * *

The Yorkville Medical Society held a meeting on the evening of November 16, one of the features of which was a symposium on periodic health examinations. Among speakers of the evening were Dr. Hyman Goldstein, Dr. Harlow Brooks, Dr. I. S. Wechsler, Dr. Herman O. Mosenthal and Dr. Charles R. Austrian.

* * *

November meetings of the New York Academy of Medicine included the stated meeting on the nineteenth when the anniversary discourse was delivered by Dr. George E. Vincent, on The Doctor and the Changing Order; the Section of Genitourinary Surgery on the eighteenth, at which a symposium on gonorrhea was held; the Section of Orthopedic Surgery on November 20th at which cases were presented by Dr. William H. Irish, Dr. Elmer P. Wiegel, Dr. Leo Mayer, Dr. Charles Ogilvy and Dr. Fred H. Albee; the Section of Obstetrics and Gynecology on the twenty-fourth, when Dr. Meyer R. Robinson read a paper on An Orientation of Biomechanism, pathology and clinical phenomena of extra uterine pregnancy, based on a study of 131 cases; the Section of Larynology and Rhinology on the twenty-fifth, with papers by Dr. Harry A. Goalwin, Dr. Sidney Yankauer and Dr. Rudolph Kramer; and the Section of Historical and Cultural Medicine on the twenty-fourth, with papers on Mementoes of Charcot and the Salpétrière, by Lt.-Col. F. H. Garetson, of Washington, and The Influence of Culture on Medicine, by Dr. Gregory Zilboorg.

* * *

The Hermann M. Biggs Memorial Lecture was given at the New York Academy of Medicine under the joint auspices of the Medical Society of the County of New York and the New York Tuberculosis and Health Association on the afternoon of November 19th. The lecturer was Dr. William H. Park, Director of Laboratories of the New York City Department of Health.

* * *

The American Prison Association held its annual meeting November 7th-14th in Jackson, Miss. One of the features of the meeting was the special attention given to the problem of prison labor, a subject of particular interest just at present in view of the intensive study of the question being carried on by the U. S. Department of Commerce. Another interesting feature was the reading of reports from delegates to the International Prison Congress in order to acquaint those present with the work being done in other countries.

* * *

The Eastern Medical Society met at the New York Academy of Medicine on November 13th. The paper of the evening was read by Dr. George W. Crile, of Cleveland, on New Conceptions of the Rehabilitation and Conservation of the Bad Risk Patient.

* * *

The Association of Italian Physicians in America met on the same date at the Academy. Dr. Angelo M. Sala read a paper on Cardiovascular Syphilis, and Dr. Salvator Di Palma one on Interstitial Tubal Pregnancy.

* * *

The New York Society for the Relief of Orphans and Widows of Medical Men held its annual meeting at the New York Academy of Medicine on November 18th.

* * *

And on the same evening and in the same building the Women's Medical Association of New York City met. The papers of the evening were by Dr. Leila Charlton Knox, Dr. Nancy Jenison, Dr. Helen Baldwin, Dr. Marie L. Chard, Dr. Connie Guion, and Dr. A. M. Pennell, of India.

* * *

The meeting of the Philadelphia Academy of Medicine and Allied Sciences on November 16th was a special meeting in honor of the contributions of deceased members. The speakers were Dr. John Turner, Dr. Eugene Hinson, Dr. De Haven Hinkson and Dr. Charles C. Dorsey.

* * *

Other important November meetings of Philadelphia societies were that of the Physiological Society on the sixteenth, at which Dr. Arman Quick, Dr. George E. Coghill, Dr. M. McCutcheon, Dr. B. Lucke, Dr. D. W. Wilson, and Dr. S. E. Kerr were the speakers; the section on otology and laryngology of the College of Physicians on the eighteenth, at which Dr. S. J. Crowe, of Johns Hopkins University was one of the principal speakers; of the section on ophthalmology on the nineteenth, at which various cases were presented; the Philadelphia Neurological Society on the nineteenth, with papers by Dr. W. B. Cadwalader, Dr. W. G. Spiller, Dr. W. J. Freeman, and Dr. S. DeW. Ludlum; and the Academy of Stomatology on the twenty-fourth, at which the address of the evening on radicular cysts was made by Dr. A. B. Vastine.

* * *

The Interstate Postgraduate Assembly of America was held at St. Paul, October 12th-16th, inclusive.

* * *

The British National Council for Mental Hygiene has recently been holding its second annual meeting in London. The British press reports that throughout all the speeches there was an insistent disposition to regard mental disturbances as simly one of the human illnesses which we meet during our normal pilgrimage through life. Sir Courtauld Thomson presided. Among the speakers were Sir Maurice Craig, Dr. W. A. Potts, Lord Birkenhead, Secretary of State for India, and Lord Southborough.

* * *

Announcement has been made that, with a contribution from the Rockefeller Foundation, a complete bibliographical abstracting service, to cover the entire field of pure and applied botany and zoology, will be established in Philadelphia in the near future under the auspices of the Union of Biological Societies of America. The headquarters of the editorial staff will be the University of Pennsylvania. The abstracting will begin with the literature of 1926, and is expected to average 35,000 abstracts a year through the collaboration of biologists throughout the world.

* * *

On Thursday, November 19th, the medical Society of the County of New York, and the New York Tuberculosis and Health Conference opened at the Hotel Biltmore, New York City, to continue through the following day. The annual dinner meeting on Friday evening closed the sessions. Among the speakers were Dr. Samuel J. Kopetsky, Dr. Wil-

liam H. Park, Dr. Edward W. Archibald, Dr. Adrian V. S. Lambert and Dr. Howard Lilianthal.

* * *

Before the closing of the British Empire Exhibition at Wembley, the Imperial Social Hygiene Congress was held, October 5th-7th, Sir Auckland Geddes presiding. The patrons of the congress were the Right Hon. L. S. Amery, Secretary for the Dominions, the Right Hon. Neville Chamberlain, Minister of Health, Lord Willingdon, and a number of Dominion High Commissioners.

* * *

Standing committees on the behavior problems have been appointed by the National Education Association, and the National Conference of Social Work. The former committee is under the chairmanship of Olive M. Jones, and the second under that of Graham Romeyn Taylor.

More than seven hundred delegates, representing thirty countries, attended the fourth International Medical Congress on industrial accidents and disease held at Amsterdam. Among exhibits shown was a metallic roentgen tube affording absolute protection to the operator.

* * *

The annual dinner of the Visual Instruction Association of America was held on November 14th at the Hotel McAlpin, New York City. The speakers were Dr. C. W. Kimmins and Dr. John H. Finley and Olive M. Jones.

* * *

Dr. S. U. Lawton lectures on Those Nerves of Ours before the Brooklyn Institute of Arts and Science on November 14th.

The sixteenth annual meeting of the National Committee for Mental Hygiene was held on November 12th at the Hotel Pennsylvania. The meeting was preceded by an informal luncheon attended by the members of the Committee, its staff, and a few invited guests.

* * *

On Saturday, November 21st, the annual exhibition of the New York Microscopical Society was opened at the American Museum of Natural History. Hours are from 7:30 to 10:30 p. m.

* * *

The National Academy of Sciences and the National Research Council of the United States have announced the publication of International Critical Tables of Numerical Data of Physics, Chemistry and Technology in five volumes. Edward W. Washburn is editor-in-chief. N. Ernest Dorsey and Clarence J. West associate editors, and F. R. Bichowsky and Alfons Klemenc assistant editors.

* * *

The annual meeting of the Alumni of the Hospital for the Relief of the Ruptured and Crippled was held November 23rd-24th at the Hotel Commodore, New York. Among the speakers were Dr. T. Turner Thomas, Dr. Allen DeF. Smith, Dr. William B. Coley, Dr. Royal Whitman, Dr. William Sharpe and Dr. Arthur Krida. Operative clinics were held by Dr. Royal Whitman and Dr. Percy W. Roberts and their staffs.

* * *

The Section of Medicine of the Buffalo Academy of Medicine met on November 11. The address of the evening on Nonsyphilitic Aortitis was made by Dr. Harlow Brooks, of New York.

* * *

Dr. Thierry de Martel, of the Pasteur Institute of Paris, was in New York recently and visited the Bureau of Clinical Information of the Academy of Medicine with a view to getting information for the establishment of a similar bureau in Paris.

* * *

At the recent annual meeting of the American Foundation for the Blind a letter was read from Mary Pickford to Helen Keller, announcing the former's intention of appearing as a blind girl in a picture of which part of the proceeds are to be donated to the Foundation.

* * *

The New York Academy of Medicine has closed its exhibit of the works of Sir Thomas Browne, and has opened one of the works of Jean Martin Charcot, born on November 25, 1825. Charcot was considered the greatest neuropathologist of France and the greatest physician of his time. The exhibits includes the Academy's copies of his works, both in collected sets and separate volumes, or special editions, and the sets of periodicals which he edited during his lifetime, including the *Archives de Neurologie* (1880-03); *Archives de Physiologie* (1868-88), and *Nouvelles Incongraphies de la Salpétrière* (1888-93).

* * *

The Travel Study Club of American Physicians has planned a "study tour" for 1926 embracing Norway, Sweden, Denmark, Germany, Switzerland, France and England. The present officers of the club are, president, Dr. Louis Livingston Seaman, of New York; vice-presidents, Dr. Fred H. Albee, of New York, Dr. Edward B. Heckel, of Pittsburgh, and Dr. John P. Lord of Omaha; secretary-treasurer, Dr. Richard Kovacs, of New York.

* * *

One of the features of the recent meeting of the American Society for the Control of Cancer, held in New York, was the decision to call a convention of fifty cancer experts in Europe next September. Specialists from Belgium, England, France, Holland and Switzerland will cooperate with specialists from this country in formulating and establishing a basis of data and opinions for the campaign against cancer. The information so obtained will be given wide publicity.

* * *

The thirty-eighth annual meeting of the Medical Society of the Missouri Valley was held in St. Joseph, Mo., September 30th to October 2d inclusive, the outgoing president, Dr. John W. Martin, in the chair. The program was a combination of hospital and diagnostic clinics, and symposia on the internal secretions, fractures, diseases of the heart, and other topics. The evening sessions were devoted chiefly to papers by the society's guests, among whom were Dr. D. T. Dunott, of Baltimore; Dr. V. J. O'Connor, Dr. S. R. Slaymaker, Dr. Robert H. Babcock, Dr. Karl Meyer, Dr. B. F. Lounsbury, of Chicago; Dr. Walter M. Boothby, of Rochester, Minn.; and Dr. Russell, Dr. Weingart and Dr. Connell, of Des Moines. Officers elected for the coming year were Dr. A. D. Dunn, of Omaha, president; Dr. H. W. Carle of St. Joseph, first vice-president; Dr. M. A. Tinley, of Council Bluffs, second vice-president; Dr. Charles Wood Fassett, of Kansas City, Mo.; secretary (re-elected) and Dr. Oliver C. Gebhart, of St. Joseph, treasurer.

* * *

Dr. Archibald Malloch, of Montreal, has been appointed librarian of the New York Academy of Medicine. Dr. Malloch is a graduate of Queens University, and took his medical degree at McGill, where he also did his early professional work as resident pathologist and bacteriologist, and as intern in medicine. He served with the Canadian Red Cross and Canadian Army Medical Corps during the war, and was later Beit Fellow at Oxford. He is a member of the Royal College of Physicians, and has been filling the positions of demonstrator in medicine at McGill, assistant physician at the Royal Victoria Hospital, and assistant editor of the *Canadian Medical Association Journal.*

* * *

At the meeting of the Medical Association of the Greater City of New York, held at the Academy of Medicine on November 16th, the subject of the evening was Surgery of the Sympathetic Nerve. Dr. Howard Lilienthal read a paper on the Influence of Cervical Sympathectomy on Angina Pectoris; The Relation of Surgery to the Vascular Sympathetic System was treated by Dr. Walter Aikman Sherwood, and Dr. Herman LeRoy von Lackum's paper was on Sympathetic Ramisectomy in Spastic Paralysis.

* * *

At the regular meeting of the Syracuse Academy of Medicine, held on November 3d, the evening's program consisted of several case reports of unusual interest, presented by Dr. E. B. Kaple, Dr. W. W. Street, Dr. J. E. Delmonico, and Dr. M. E. Holmes.

* * *

The cornerstone of the new building of the New York Academy of Medicine on the corner of 103rd Street and Fifth Avenue was laid with due ceremony and impressiveness, in spite of the inclement weather, on the afternoon of Friday, October 30th. The casket placed in the stone contained copies of the daily papers of that date, the coins of the realm, a copy of the constitution and bylaws of the Academy, and a list of the founders. After the spreading of the mortar by the architect, Dr. Samuel Brown, the president, was presented with a silver trowel, with which he com-

pleted the process of sealing the stone in its position. Dr. Brown made a brief address and introduced Dr. George D. Stewart, the orator of the occasion. Dr. Stewart declared, however, that on account of the bad weather, he would keep his address in his pocket. He extended hearty thanks to all who had helped in making possible the new building for the Academy, especially Dr. Pritchard and the Rockefeller Foundation for their bequests.

The Joint Committee on Methods of Preventing Delinquency, New York City, has recently issued an inferesting publication covering the work of the various divisions of the Commonwealth Fund Program for the Prevention of Delinquency, beginning with the adoption of the program in November, 1921.

* * *

Prof. Edmund B. Wilson addressed the members of the Biology Section of the New York Academy of Sciences at the regular meeting on November 9th. His subject was Modern Problems of the Cell.

* * *

For the benefit of the Neurological Institute of New York, an international hockey match between the Canadians of Montreal and the New York Hockey Club has been arranged for the evening of December 15th at the new Madison Square Garden. The event will open the New Garden, and many prominent Canadians are expected to be present. The hockey match will be preceded by an exhibition of figure skating by well known professional skaters.

* * *

At the meeting on November 9th at the Academy of Medicine of the Society of Medical Jurisprudence, Dr. Spencer L. Dawes and Dr. Sanger Brown discussed the medical and legal related to defective and insane emigrants.

* * *

The Association to Promote Proper Housing for Girls helds its annual conference November 16th-17th at the Hotel Pennsylvania, New York. The general subject designated for discussion was Lack of Home Environment in Relation to Crime and Other Social Problems. On Monday, the sixteenth, a luncheon was tendered to guests and members at which Hon. Edward F. Boyle of the Children's Court was one of the speakers. Others who made addresses at the luncheon were Dr. Amos T. Baker, superintendent of the Bedford Reformatory, and Virginia M. Murray, general secretary of the Travellers' Aid Society. A conference of landladies was held on Monday evening, a conference of room registries on Tuesday afternoon, and in the evening an oratorical contest for girl speakers, representing various organizations and institutions, on the subject of Where To Live.

* * *

The Jewish Mental Health Society's conference was held on November 12th. Dr. William A. White, of Washington, D. C., addressed those present on the subject of Crime and Insanity.

* * *

Dr. C. R. Orton delivered an interesting lecture on Seeds as Carriers of Disease at the Museum Building of the New York Botanical Garden, Bronx Park, on November 16th.

* * *

A course of fifteen lectures will be given at the New York Academy of Medicine on Tuesday afternoons at four o'clock, November 10th to March 2nd, inclusive, under the auspices of the National Committee for Mental Hygiene. On November 10th, Dr. Edward Grant Conklin, professor of biology at Princeton, spoke on Development in the Light of Heredity and Eugenics; on November 17th, Patty Hill, professor of education at Teachers' College, Columbia University, discussed Mental Hygiene and the Nursery School; on November 24th, Dr. Douglas A. Thom, of the Massachusetts Department of Mental Diseases, gave a paper on Mental Health and Habit Training; on December 1st, Dr. Thom spoke again on Habit Clinics for Problem Children. The list of succeeding lectures and lecturers follows in chronological order. Some of the Emancipation Problems of the Adolescent, by Dr. Thomas W. Salmon; The Mental Health of the School Age Child, by Dr. Ira S. Wile; Juvenile Delinquency and Mental Hygiene, by Augusta F. Bronner, Ph.D.; Mental Hygiene as a Preparation for College Life, by Dr. Arthur H. Ruggles; Mental Tests, by Paul Klapper, Ph.D.; Applying Mental Hygiene to the Community, by Stanley P. Davies, Ph.D.; Inheritance of Mental Disease, by Dr. Abraham Myerson; Individualism and Mental Health, by Dr. Adolf Meyer; New Concepts of Mental Health, by Dr. C. Macfie Campbell; Relation of Nervous Disorders to Functional Disease, by Dr. Foster Kennedy; Psychological Methods of Cure, by Dr. William A. White.

* * *

The Personnel Research Federation, organized in 1921 to further research activities pertaining to personnel in industry, commerce, education, and government, wherever such researches are conducted in the spirit and with the methods of science, has recently held an exhibit of selected publications issued by its corporate members. Among these are the Engineering Foundation, American Federation of Labor, Bureau of Vocational Information, Vocational Service for Juniors, American Telephone and Telegraph Company, Western Electric Company, National Research Council, National Committee for Mental Hygiene, Carnegie Institute of Technology, the U. S. Public Health Service, the Civil Service Commission, Bureau of Mines, Bureau of Labor Statistics, and a number of leading universities of the country.

* * *

The fourteenth convention of the Societâ Italiana per il Progresso delle Scienze was held under the chairmanship of Professor Solari, Rector of the University of Pavia, during the recent celebration of the eleventh centenary of that venerable institution. The university was founded by the Emperor Lothaire in 825 A. D.

* * *

A dinner was held on November 23rd at the Waldorf-Astoria to inaugurate the national campaign for the endowment fund for the projected National Home for Aged and Needy Physicians.

* * *

The Veterinary Medical Association of New York City met on November 4th at the New York Academy of Medicine. Dr. Maurice C. Hall, chief of the Zoological Division of the U. S. Department of Agriculture, spoke on Anthelmitic Medication. A number of interesting case reports were given.

* * *

At the recent convention of the National Council of Women held in Detroit, Dr. Valeria Hopkins Parker, of New York City, was elected president. Dr. Parker is a graduate of Hering Medical School, Chicago, and among other important offices has held those of executive secretary of the U. S. Interdepartmental Social Hygiene Board, Chairman of the Social Hygiene Committee of the League of Woman Voters, and staff member of the American Social Hygiene Committee. She was also the first State policewoman in the United States, having held office in Connecticut.

* * *

The Union Health Centre of the International Ladies' Garment Workers' local unions in New York City celebrated its fifth anniversary on November 6th with the opening of a new dental clinic. Dr. Frank Monaghan, City Health Commissioner; Porter Lee, of the New York School of Social Work, and Mrs. Sara Conboy, secretary of the United Textile Workers' Union, were present. A special department for children, equipped with all the latest means for doing preventive and corrective work, is one of the features of the new clinic.

* * *

The first international conference for the Young Men's Christian Association held since the war will take place in August of 1926 at Helsingfors, Finland. Among subjects to be brought before the conference are sex life and social hygiene, applied psychology and problems of the home, of work, and of marriage.

* * *

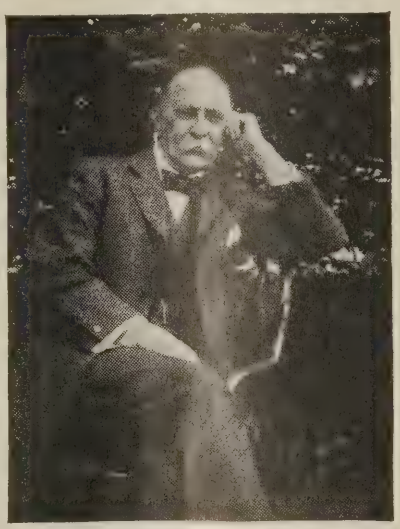
One of the features of the recent International Statistical Congress held at Rome, Italy, was the address of the great Italian criminologist., Dr. Enrico Ferri. Dr. Ferri's thesis was a comparison of the figures of murders and suicides, a comparison of these two forms of abnormal human conduct, and a statement of the direct relation which he believes exists between them. As a preventive of murder, Dr. Ferri advocated strongly the abolishment of capital punishment, stating that, ever since its abolishment in Italy thirty-five years ago, murders have distinctly decreased.

Book Reviews

OSLER

The Life of Sir William Osler. By Harvey Cushing, M.D. Two Volumes, with illustrations. Oxford Medical Publications. London and New York: Oxford University Press, 1925. Pp. 1413.

Osler believed in the fullest recognition of merit, whether of intention or achievement. All his life he delved into the histories of bygone makers of medicine, and it is more than fitting that this biography of the man Osler should at the same time serve as a monument to his predecessors. Medical history is bound up in this book of Osler's life, while a detailed picture of the medical profession detaches itself from the utterances of this all comprehending historian. One marvels at the concentration of the man, the limitless activity of his mind, the skill with which he turned everything to account. A lesson in economy and adaptation that he must have gained very early in his studies of the microscopic animal world.



SIR WILLIAM OSLER

Cushing's biography is invaluable not alone for the record of Sir Williams's remarkable life. It shows medicine all over the globe, medicine in its making seen through Osler's penetrating eye; it covers the period of epochmaking experiment and advance. It shows moreover how a man can have infinitely much to do and still do it well and crowd more in besides. No thought of self and an eight hour day here. He often drove himself past the limits of endurance, yet the will never failed him. He always accomplished what he wanted probably because he made a point of knowing just what he wanted, driving straight for the goal. He did not hesitate to change his goal if he doubted it. He was truthful with himself, and his chief inspiration was the welfare of the medical profession.

Thus much of his qualities as a man. A scientist with a genius for organization is a rare bird. But Osler adapted his inclination to his training, his opportunities to his inclination with the remarkable result of being able to see medicine as a whole, and his own share in it an infinitesimal part that nevertheless required constant rounding out and adjustment to all the other component parts.

The study of Osler as a man which is afforded by this complete biography makes us more keenly appreciate the quality of work he did in the clinic and in his writings. We better understand the manner of his attack on any particular subject and our contact with his works becomes more personal. The greatest value of the biography aside from the work itself is in its enhancement of his own works to the student. A reading of this work should serve as an inspiration to the physician and as a stimulus to him as he plods along through the many thankless tasks of everyday medicine. When he is confronted by the conflict of gain or progress he can think of Osler and so make his task less complicated.

This biography would seem to us as essential an item in every medical library as Osler's own *Practice of Medicine.*

THE ART OF MEDICAL TREATMENT

The Art of Medical Treatment. By Francis W. Palfrey, M.D. Philadelphia and London: W. B. Saunders Company, 1925. Pp. 463.

The author has made a laudable attempt to place almost all that is known in medicine in one small volume, which is of course impossible. He has, however, produced a book that is full of useful suggestions and that outlines orthodox treatment of disease. His "First Thoughts," and his "Placing" captions are novel and suggest thoughtful judgment on the part of the attending physician.

The etiology of the various diseases is not sufficiently discussed, and hence the chief line of curative or combative treatment is not enough emphasized.

A few concrete thoughts that occur to the reviewer may not be amiss. Under the treatment of typhoid fever he says that abdominal distention must be avoided. He is correct. Tympanites is not a symptom of typhoid fever, it is a complication, and when it occurs, almost invariably shows a mistake in the treatment or feeding of the patient.

Chorea should never be classed with the nervous diseases. It should be classed as an infection, similar to acute arthritis. The author is correct in stating that arsenic is of doubtful value in this disease. On page 119, discussing the treatment of colds, he says that "most doctors smoke throughout colds without obvious harm." It might also be noted that most doctors do a lot of fool things and survive.

The author's next edition might well omit anorexia nervosa and valvular cardia as unworthy of separate description.

In his discussion of pernicious anemia and leucemia the author starts in with radical treatment without at all discussing focal infection as being the most frequent cause, especially mouth infection. In fact, any discussion of diseases of the blood is worthless unless the importance of mouth infection or the absence of mouth infection is noted. The treatment of pernicious anemia with arsenic and transfusion is not enough.

Purpura should rather be regarded as due to infection than "as a curiosity in the course of primary disease."

He does not sufficiently discuss neurocirculatory asthenia. It is a large subject, and many will not agree with him in stating that "as seen in soldiers it seems to be a manifestation of subconscious fear."

The reviewer suggests that in the next edition either hyperthyroidism be not discussed at all or that much greater detail be given to the many forms of this very important condition.

Even in a book of this size the treatment of the epileptic should not be outlined until many suggestions have been made as to possible causes, perhaps infection or disturbance of the endocrine glands. In other words, the management of an epileptic is a very large subject.

RESPIRATORY METABOLISM

Die gasanalytische Methodik des dynamischen Stoffwechsels. Von Priv.-Doz. Dr. Wilhelm Klein und Maria Steuber. Mit 20 Abbildungen. Leipzig: Georg Thieme, 1925. Pp. 99.

In this brochure the authors report upon the methods used by them through years of experience with the technic of studying the respiratory metabolism. As the results of the study of respiratory metabolism are not sufficient in themselves for the determination of the true metabolic procedures in the body, it is necessary to determine also the elementary constituents of the food, the feces, and the urine.

The significance of psychic influences, the physical properties of gases, the solubility of gases in fluids, the collection and preservation of gases, the cleansing of the mercury, and the apparatus used are discussed. The latter are of two types: 1, those used for purely physiological purposes, such as the Pettenkofer-Tigerstedt, the Regnault-Reiset, and the Zuntz-Geppert; 2, those that are suitable mainly for clinical purposes, as the Benedikt and the Krogh apparatus. The technic in the use of each one of these apparatus is described in great detail.

There is little of practical value to the general practitioner in this brochure but one who has opportunities of using these methods will find much valuable material in it.

THORACIC EMPYEMA

Some Fundamental Considerations in the Treatment of Empyema Thoracis. By Evarts A. Graham, A.B., M.D. St. Louis: C. V. Mosby Co., 1925. Pp. 110.

This volume of only a little more than a hundred pages contains a brief but thorough discussion of the pathology and the surgical methods which should be resorted to to prevent an empyema from becoming chronic. In the chapter on pathology, the author maintains that the prevalent conceptions of mechanics of open pneumothorax are erroneous, and by experimental work shows the equality of relative densities of both lungs in unilateral open pneumothorax. This chapter requires careful reading to understand the theories of the author which are disputed in certain circles. In the later part of this chapter he discusses the advantage of repeated aspiration compared with early continuous drainage and comes to the conclusion that if early continuous drainage is to be carried out it would seem that the simplest possible procedure should be employed, as, for example, some one of the methods which are based on the principle of the insertion of a drainage tube through a cannula between the ribs with the later withdrawal of the cannula.

As to when and what kind of operation should later on be performed, he maintains that a convenient criterion is the presence of frank puss. The Empyema Commission of the United States Army during the war, of which Dr. Graham was a member, found that usually a period of from two to three weeks elapsed from the time of the onset of a streptococcal pneumonia to the appearance of definite frank puss, during which time usually about four aspirations had been made. An excellent bibliography on the subject completes this well written treatise which the author himself admits does not cover the subject of empyema in an exhaustive manner, but any surgeon who studies carefully the theoretical basis for the treatment of empyema as outlined by the author, will admit its soundness. The work received and amply deserved the Samuel D. Gross Prize for Surgery for the year 1920.

FATS

The Fats. By J. B. Leathes, M.A., M.D., F.R.S., and H. S. Raper, C.B.E., M.D., Ch.B., D.Sc. Second Edition. London and New York: Longmans, Green and Company, 1925. Pp. 242.

The second edition of this useful monograph on the fats has been thoroughly revised, and the text and bibliography brought up to date. Inasmuch as another monograph in the same series covers the phospholipines, these substances, so important in the metabolism of the body, have not been included. The last chapter on the parts played by the fats in the life of the cell is a useful survey of our knowledge at the present time.

THE DIGESTIVE PROCESS

Experimentelle Physiologie und Pathologie der Verdauung (Chymologie). In dreissig Vorlesungen von Prof. Dr. E. S. London, Leningrad. Mit 16 Abbildungen im Text. Berlin-Wien: Urban & Schwarzenberg, 1925. Pp. viii-197.

This monograph consists of a series of lectures given by the author. It is based on a personal experience of many years in laboratory investigations. The main endeavor of this publication is to show what problems in digestion have already been solved with the aid of experimental operative methods and what problems still await solution.

The process of the digestive mechanism, as they occur in the various parts of the digestive tract, are given in great detail. The changes resulting from the surgical removal of various parts of the digestive tract are described. The student of the digestive process will find much valuable material within these pages.

ACUTE ABDOMINAL DISEASE

Clincal Researches in Acute Abdominal Disease. By Zachary Cope, M.D., F.R.C.S. Oxford Medical Publication. Illustrated. London and New York: Oxford University Press, 1925. Pp. 148.

This book of less than 150 pages offers a fascinating treatise to those interested in abdominal diseases. The introductory chapter on the Scope of Clinical Research is followed by sections on the Parietal Peritoneum and the Localization of Pain, on Muscular Rigidity on Cutaneous Hyperesthesia and on Phrenic Shoulder Pain. There are also interesting chapters on the differential diagnosis between acute thoracic and abdominal lesions, on genitourinary symptoms in appendicitis, on the femoral test for hypogastric peritonitis, and on perinephric abscess occurring without disease of the kidney.

The work is well illustrated by numerous diagrams and sketches.

EYE DEFECTS FROM SKULL INJURIES

Ocular Defects Arising from Skull Injuries. Bureau of Workmen's Compensation Bulletin, No. 10. By John S. Somberg, M.D. State of New York, Department of Labor, 1924. Pp. 49.

This is a résumé of the study of ocular defects from skull injuries as met with in the Medical Department of the State Department of Labor. It is based largely on the author's personal experience for the last one year and a half, and to this are added records of previous years. The subject matter is of great importance, especially to those engaged in industrial accident work, and the practical value of the author's findings would be considerably enhanced by the inclusion of illustrative cases to elucidate the text much more fully. A dry, textbook enumeration of pathological conditions is not apt to leave much of an impression on the reader's mind.

PARASITOLOGY

Parasitology for Medical Students. By Alex. Mills Kennedy, M.D. (Glas.), Professor of Medicine, University of Wales. Oxford Medical Publications. London and New York: Humphrey Milford, Oxford University Press, 1925. Pp. 7-142.

This book is based on the author's clinical teaching, and is designed for medical students and practitioners rather than for those desiring to specialize in parasitology. The colored plate and the microphotographs are original with one exception. The subject material is divided into chapters on insects and arachnids, tapeworms, flukes, roundworms, protozoa, and spirochetes and fungi.

The parasites and their life habits are described, including also the methods of destroying them. The symptomatology, diagnosis, prophylaxis, and treatment of the disease caused by the different parasites are given concisely.

OPHTHALMOLOGICAL LITERATURE

The Ophthalmic Year Book. Volume XXI. Edited by William H. Crisp. Assisted by Thirty-Three Collaborators. Ten Illustrations in the Text. Chicago: The Ophthalmic Publishing Company, 1925. Pp. I-X, 1-323.

This annual index of ophthalmological literature has become an indispensable aid to every eye man who aims to keep abreast of the literature of the world. The most important contributions of permanent value are duly catalogued and digested, and so systematically arranged as to authors and subjects that the reader is easily enabled to lay his hand on any subject desired. More and better executed illustrations would greatly enhance the value of the text.

DISEASES OF THE EYE

Ocular Therapeutics. By Dr. Ernst Francke. Translated by Clarence Loeb, A.M., M.D. St. Louis: C. V. Mosby Co., 1925. Pp. 1-183.

This little volume is devoted to the teratment of ocular affections (exclusive of optic and operative therapy) in a manner as full as it is concise and practical. The book is divided into two large parts, the first occupying itself with general subjects, such as tuberculosis, syphilis, serotherapy and organotherapy, ray and light therapy, and electric treatment, while in the second part the treatment of diseases of the eye is taken up seriatim. The work is eminently practical, fully abreast of the times, and can be recommended as an excellent therapeutic vademecum in the oculist's daily work. The translation is well done.

THE FOUNDATIONS OF MEDICAL SCIENCE

Das Wesen der Heilkunde. Historisch-Genetische Einfuhrung in die Medizin. Fur Studierende und Arzte. Von Dr. Georg Honigmann. Leipzig: Felix Meiner, 1924. Pp. 319.

A critical survey of the requirements of medicine, including the necessary background for the physician. Here we have a recapitulation of what the author feels should be the foundations of every medical man. He includes the required studies and how they should be incorporated into the mind or makeup of the doctor and an attempt at a better understanding of the environmental conditions—structural, economic and personal.

The author writes in a clear editorial like fashion and is frequently more easily followed than agreed with. Nontheless he has many original points of view and anyone familiar with German would do well to look over this small monograph.

BACTERIOLOGY

A Textbook of General Bacteriology. Eighth Edition, Thoroughly Revised. Fully Illustrated. By Edwin O. Jordan, Ph.D. Philadelphia and London: W. B. Saunders Company, 1924. Pp. 752.

The eighth edition of Jordan's *Bacteriology* is not much changed from previous editions. The book still retains the form in which it was originally printed, the author having resisted the temptation to increase the size of the volume by the addition of technical procedures. Instead, the student is referred to standard works for all matters concerning the preparation of media and the details of cultivation of organisms. The public health aspects are well dealt with. The whole forms an excellent general text for the student.

CHEMISTRY IN MEDICINE

Physical Chemistry in Biology and Medicine. By J. F. McClendon, Ph.D., and Grace Medes, Ph.D. Philadelphia and London: W. B. Saunders Company, 1925. Pp. 425.

It is high time that the scattered material on physicochemical investigation of the last few years, as it applies to general biology and medicine, should have been collected in convenient form. The senior author, a well known worker in the field, is admirably equipped for the purpose. The essentials of the subject have been very simply explained, and any deficiency in its handling has been made up by the complete bibliographies at the end of each chapter. The physician who talks glibly about the pH of the blood without knowing in the least what "pH" means, or how it is obtained, can find a simple explanation in chapter 5. It is doubtful if he will read much of the rest of the book.

LORD BYRON

Glorious Apollo. By E. Barrington. New York: Dodd, Mead and Company, 1925. Pp. 371.

The explanation of behavior has become one of the most fascinating of literary pursuits. And while many writers sense the underlying motives, the real treat comes to the scientific reader with interpretive training confronted by such rich fare as Barrington's *Glorious Apollo.* The Byron mystery has been acutely relived, a theory formed, and every attainable fact marshalled to support the theory. Byron remains inexplicable. But the victim of years of misrepresentation and misunderstanding comes close to

writer and reader in a new and sympathetic light.

The chief cause for the mystery surrounding the Byron case was the feeling that the actors in that moving drama behaved contrary to all known rules of psychology. Recent discoveries in the psychoanalytic field, to which the writer must have had access in preparing her detailed "case history" mark this "incomprehensible" behavior as inevitable in the characters so lucidly described.

Here was a man with the emotional instability of a child, a neurotic inheritance, a mind unhampered by repressions, limitless in its resources but radiating its entire energy about the child ego. Here was a woman, healthy and normal, safe for the fashionable masochistic bent. Her perfectly normal leaning towards misery was roused to fanatic heights by her husband's component sadism. If either had had less of his or her preponderating trait an adjustment might have been reached. If Lady Anne could have taken the whip hand, and Byron sated for a time his unconscious craving for effeminate selfpity, the tragedy might have ended otherwise.

After the Byron separation each proceeds in a characteristic way, characteristic, that is, to those who can read below the surface, quite mad to those whose complexes bind them too closely to the strugglers to see clearly for themselves. Lady Anne immolates herself, Byron continues in the process of disintegration, a process inevitable with his self-centred, preadolescent emotional make up. His literary gift undoubtedly delayed the final collapse. The outlet through his writings might have proved his salvation, but it was and always had been turned to destructive ends.

Such situations are dealt with harshly today by the new psychology. Byron and Augusta Leigh would have been left to shift for themselves much more readily than a hundred years ago. Lady Anne would be justified and commended for putting aside drags upon herself and her potentially useful existence. We know today that we have the right to force people to work out their own salvation or perish in their folly. We only harm them by continuing our masochistic agitations about them.

Medicoliterary Notes.

Vienna has a new journal entitled *Biologia Generalis.* The editors are Leopold Löhner, Dr. Raymond Pearl and Valdislav Ruzicka.

* * *

A book of the month published by Macmillan is Karel Capek's *Krakatit,* a novel telling the strange story of a man who made a discovery so full of horrible potentialities that he endured persecution and many dangers in order to preserve his ruinous secret. The Neighborhood Playhouse has announced that Krakatit in dramatic form will be one of its early productions. The author, Capek, is well known through his plays already produced in New York, *The World We Live In, R. U. R.,* and *The Makropoulos Affair.*

* * *

An invention of unusual interest to the medical profession was demonstrated recently by the Columbia Phonograph Company, New York City. This was a device for the accurate recording of heart sounds, particularly the murmurs on which diagnosis is based. This should be of special value in medical schools, in that the various types of sounds may be reproduced in the classroom, and also to physicians practising at a distance from large clinics, who will be able to have sets of records illustrating all the kinds of sounds, for use in diagnosis. The invention is the product of the work of the Bell Telephone Laboratories, the Columbia Phonograph Company, Dr. Richard C. Cabot, of the Harvard School of Medicine, Dr. Horatio Burt Williams, of the New York College of Physicians and Surgeons, and Dr. J. C. Gamble of the School of Medicine of the University of Pennsylvania.

* * *

Police headquarters in New York have a bronze roll of honor of policemen who have lost their lives while on duty. This tablet is a document of unusual interest. It shows that eighty-three policemen have been killed in the performance of their duties since records began to be kept in 1854. It shows that more policemen have been killed here in the last five years than were killed in the fifty years between 1854 and 1904. Forty-three policemen were slain in the last decade, as against forty in the sixty-one years preceding. The era of reckless shooting of policemen by bandits began in 1921, in which year six policemen were killed. The highest number were slain in 1922—ten in all. Four were killed in 1923 and 1924, and in 1925 so far three have lost their lives. This list does not include the names of those policemen who were wounded and then partly recovered, but died a few months later from the effects of the wound. —*N. Y. Times.*

* * *

The *State Hospital Quarterly,* published by the New York State Hospital Commission, contains an interesting article on the psychiatric examination of a child, prepared by the Division on Prevention of Delinquency of the National Committee for Mental Hygiene. The article contains suggestions for such an examination, with particular emphasis upon the psychiatrist's attitude, and an outline for such a study.

* * *

New York playgrounds and community centres outnumber those of all other states. The total is 858. Massachusetts has 706 playgrounds and Pennsylvania 687.

* * *

A report has recently been made public by a committee of professional men appointed by the Ministerial Association of Vancouver to investigate the results of socalled faith healing. They found that of 278 supposedly cured persons who were examined, only five seemed to have made any improvement. No improvement could be found in the condition of 212, although they had declared themselves "cured," and twenty-two were distinctly worse than they had been before going to a "healer." Thirty-nine had died.

* * *

The dreaded foot and mouth disease has appeared among the cattle of several English counties, including Cheshire, Lancashire, Yorkshire, Derbyshire and Staffordshire, and these counties have been quarantined by the Ministry of Agriculture.

* * *

The National Plant, Flower and Fruit Guild, with headquarters in New York, is carrying on a campaign to encourage the use of living trees planted in pots for Christmas trees, with a view to lessening the annual destruction of potential evergreen forests in the United States. It has been announced that more than twenty chambers of commerce, rotary clubs and other organizations are coöperating to put the plan in operation in their various cities, and that two State governors, those of Nebraska and Arkansas, have endorsed the plan, as well as the American Forestry Association and the American Tree Association.

* * *

Two residents of Utah have succeeded in making grow and bear fruit grains of corn and wheat found deeply covered in the original habitations of cliff dwellers. Scientists have placed the age of such grain at from 900 to 1,200 years. The tallest stalk grown from the corn measured more than seven feet and the smallest four. Each stalk produced more than one ear of corn, while the native corn grown fifty feet away produced only one ear to a stalk. Some of the plants had as many as five ears, and bore leaves nearly five inches wide. Another farmer purchased a seed of wheat found in an ancient cliff dwelling, planted it in 1923, and in 1924 harvested several bushels from the original kernel.

* * *

A resolution has recently been presented to the Reichstag to make compulsory the sterilization of unmarried mothers.

Dr. Boeters, author of the resolution, includes in his so-called defective class all deaf, dumb or blind children of a mentality below the average; morally irresponsible adults; and those afflicted with hereditary deafness or blindness. The last class would be permitted to marry only after they had been awarded a certificate of operation. The resolution reads in part: Women and girls who have borne more than one child, whose father cannot be determined, are to be examined, and, if it is found that their mentality is below normal, they are to be made sterile or kept in public institutions until they are past the child bearing age.

* * *

We Must March, Mrs. Honoré Willsie Morrow's latest novel, is based on the diary of Narcissa Whitman, wife of Dr. Marcus Whitman, who went with his bride to the Columbia River region in 1836. In the same party was Eliza Spalding, bride of Dr. Whitman's associate. They were the first white women to cross the Rockies.

* * *

The Carnegie Institute of Washington has established a monkey colony in its embryological laboratory where for the first time in the history of science monkeys will be observed and studied in succeeding generations of their families under conditions as similar as possible to those of their native jungle. One of the chief objects of the colony will be the investigation of the theory of man's descent from the higher apes. The colony will consist of macaque monkeys, for, although these are not so similar to man as the anthropoid apes, they are more readily available, the climate of their habitat—Asia—is somewhat like that of this country, the cost of obtaining and keeping them is comparatively small, and they are small and have tractable and amiable dispositions tending to facilitate study of themselves and their manners and customs.

The latest report of the California State Bureau of Labor Statistics states that 5,000 children were engaged in agricultural pursuits in that State at the time of submission of the report. The census report of 1920 showed only 1,832 children so engaged. The bureau found many children working in the cotton fields of Fresno County and the Imperial Valley. It recommends amendments to the California child labor and school attendance laws in an effort to better these conditions.

New York State has added to its laws during 1925 a number of important provisions relating to the discovery, education, care and treatment of physically handicapped children. Boards of education and trustees of schools are authorized to provide transportation, home teaching, special classes or schools, scholarships in nonresidence schools, tuition and maintenence in elementary, secondary, higher, special and technical schools, and, upon recommendation of the State Health Department, surgical, medical or therapeutic treatment, hospital care, braces and other appliances for them. The State Department of Health is required within the limits of the appropriation made for the purpose to cause physical examinations to be made of physically handicapped children "prospectively or actually incapacitated for the normal pursuit of an education."

Wild animals in South Africa are decreasing so rapidly, due to their hunting with motor cars, long range magazine rifles, and search lights, that the government has been aroused to take steps toward stopping the wholesale slaughter. The former Minister of Lands has been making an eloquent appeal in Capetown for the preservation of the mere remnant of a herd of elephants, the only ones left in the Union, which the farmers are destroying by cutting off their water supply. The white rhinoceros is practically extinct already, as are many species of antelopes, the mountain zebra, the black rhinoceros, the eland, and many other animals of the socalled big game class. The Sabi Game Reserve, established by President Kruger, is quite small, and those interested in the movement are trying to bring about its extension to a much larger scale that will help at least to protect and preserve some of the most interesting and beautiful animal life of the world.

A prohibition movement is rapidly spreading and gaining strength in Hungary. It is being sponsored by the Good Templars and the Blue Cross Association. The aim of the former organization is to establish a completely dry Hungary, while the latter are fighting only against alcoholic excesses. Questionnaires have been sent out throughout the country asking the expression of an opinion from responsible individuals and organizations on: 1, That all public houses and inns be closed from Saturday at 2 P. M. until Monday at 8 A. M.; 2, That all inns selling brandy alone be abolished; 3, That youths under eighteen shall not be served with alcoholic drinks in licensed establishments.

The Children's Bureau of the U. S. Department of Labor has recently issued a report on laws relating to sex offenses against children as Publication No. 145. It includes abstracts and texts of state age of consent laws and of laws relating to abduction, seduction, prostitution and other sex effenses in regard to minors. The text of the Federal laws that have some bearing on the subject, as for instance the laws relating to the white slave traffic, or to the transportation of aliens for immoral purposes, is also included. Another legal report of significance to child welfare workers is soon to be issued by the Children's Bureau—a report on adoption laws in the United States. A preliminary analysis of the development and character of adoption legislation in this country is followed by the text of sections from recent adoption laws of various States.

While Mars was comparatively a near neighbor last summer, Dr. W. W. Coblentz, of the Bureau of Standards, was able to make some interesting observations of the surface of the planet and to draw some equally interesting conclusions. With the use of an extraordinarily delicate instrument, he reached the conclusion that the mean annual temperature on the surface of Mars is about 20° F., compared with the earth's 59°. The mercury can descend frequently to 100° below zero. A noonday temperature at the equator, where there is vegetation, might rise as high as 65°. Dr. Coblentz concluded that at night the surface temperature on Mars is about 70° C. below zero, or about 50° F.

Abstracts from Current Literature

GYNECOLOGY AND OBSTETRICS

Tubal Inflation in Sterility.—Lawrence M. Randall (*Medical Clinics of North America,* January, 1925) asserts that there is no doubt that tubal inflation (transuterine pneumoperitoneum) is an important and practical addition to our armamentarium for the diagnosis of the etiology of sterility in women. If reasonable care is exercised in the selection of cases, no untoward results may be expected from the inflation. In none of the patients subjected to this test in the Mayo Clinic have complications arisen as the result of its employment.

The author is not prepared to make, as yet, a definite statement concerning the therapeutic effect of tubal inflation. In a certain number of patients, occluded tubes have been opened by this method, in some of whom occlusion was the only factor which could be found to explain the failure to conceive. It would seem logical to expect pregnacy to occur in these patients.

In the author's cases, the history was one rather commonly met with in sterile women, that of a low grade and apparently insignificant infection, following either abortion or delivery. It is not possible to demonstrate gross lesions in such patients, but with the inflation the fallopian tubes are found to be closed. The author believes that these cases should be subjected to at least six tubal inflations before operation is advised. In a few instances the tubes have apparently been opened with gas under pressure.

The Ovarian Hormones.—R. Courrier (*Revue Française d'Endocrinologie,* March, 1925) believes the hormone which regulates the menstrual cycle is contained in the liquor folliculi. He names it *folliculine.* Injected into female animals castrated months earlier, it induces in a few hours the characteristic manifestations of the follicular phase of genital life immediately following the estrus. In the author's experiments the reaction was not confined to the vagina, where the injection was made, but was characteristically manifest also in the mammary glands, the salpinx, and the uterus. Chemical analysis shows folliculine to be soluble in alcohol, ether, acetone, and benzine. It does not seem to be a phosphatide, but rather to belong with the neutral fats and cerebrosides. An interesting fact is seen in its action before arrival at puberty. In animals only a few days old the vaginal epithelium proliferated intensely when injected with folliculine. But even beyond this, injection of a pregnant female near term affected the vagina of the fetus in the same way. In conclusion, the author affirms that the ovary secretes at least two hormones, the follicular hormone and a luetic hormone. The first he has now isolated; the second has not yet been identified, but is unquestionably of equal importance.

Eclampsia Statistics from the Clinic of the University of Helsingfors.—Laimi Leidenius (*Acta Societatis Medicorum Fennicæ Duodecim 1925, Tom VI, Fasc. 3*) gives a survey of eclampsia cases occurring during fourteen years, from January, 1911, to December, 1924, and as the Finnish women incline more and more to hospital care during parturition—there being only 184 confined at home in 1923 against 891 in 1911—the 204 cases treated at the University clinic and the ninety-three at private sanatoria practically comprise the eclampsia cases in the city of Helsingfors with a population of 200,000. Only those having actual convulsions are enumerated and the occurrence of eclampsia in the series of 40,413 births was 1 to 166 or 0.60 per cent. While the author finds from his observations that toxemia of pregnancy is on the decrease, the statistical curve of eclamptic morbidity shows two sharp upturns during the period studied, one being in direct relation to the havoc and food scarcity due to war, the other coincident with an epidemic of encephalitis lethargica, and this would seem of significance in searching for the etiological factors that predispose to eclampsia. Thus the same condition of the brain that predisposes to encephalitis might prepare the soil for eclampsia, and similarly the psychic disturbance due to war would lower the resistance of the nervous system to unfavorable influence, including the toxemia of pregnancy. In contrast to this, the obstetrical annals of some other countries show a diminution of eclampsia during war, the inference being that the scarcity of meat and the laborious outdoor life that the exigencies of war imposed upon some women were of benefit. That eclampsia is not infrequently associated with contracted pelvis is borne out in the 204 tabulated cases, which also showed a larger proportion of undersized women than was noted among other parturients, and that some inherent constitutional inferiority, manifesting itself in anomalies of the physical organism, has a bearing upon the incidence of eclampsia, is a conclusion arrived at by the author.

That eclampsia is preeminently a disease of primigravidæ was also noted in the clinical study, there being five times as many cases as in plurigravidæ. The clinical course shows the proportion of eclampsia cases to be seventeen per cent. in pregnancy, fifty-eight per cent. during labor and twenty-four percent. in the puerperium, the latter being mostly pluriparæ. Albuminuria was present in high degree in seventy-nine per cent. of the cases and absent in nine per cent. Marked edema occurred in thirty-eight per cent. The blood pressure was 130 to 205 excepting in twelve per cent. of the cases, where it did not exceed 120, but there was no relation between the blood pressure and the severity of the case. Among the factors that have brought about a decrease in eclampsia among Finnish women are prophylaxis and treatment in the preeclamptic stage, made possible since gravid women more and more acquire the habit of consulting physicians; also the more rational underwear of modern times is thought to be of moment, especially in the windy Helsingfors. Treatment consisted in isolating the patient in a dark room with icebag on head and narcotics more or less—mostly morphine and chloral—according to Straganoff's method. Venesection was practised in the majority of cases, from four hundred to six hundred c.c. once, rarely twice. In cases of moderate severity low or medium forceps were applied as indicated. In deeply toxic cases where the patient was comatose with many convulsions, high blood pressure and scant urine together with undilated cervix, the procedure was operative delivery without delay. In 154 cases with antipartum eclampsia twenty-seven gave birth spontaneously, thirtv-four were delivered by low and medium forceps, seventeen had high forceps, version or craniotomy, fifty-six had cervical dilation with operative extraction; abdominal Cæsarean section was done in nine cases and vaginal Cæsarean in six. For rapid delivery the author finds Cæsarean section most satisfactory, contrary to the experience of Heinlein and Hinselman. For cervical dilatation the Champétier bag was used in some cases. Subsequent to 1915 Von Wichman's dilator was largely used, being much safer than the Bassi dilator.

The maternal mortality in the series studied was 14.2 per cent. and the child mortality 34.3 per cent., being somewhat lower than contemporary statistics from some other hospitals, namely, the Rudolf Virchow Krankenhaus in Berlin and the Essener Frauenklinik, but Forssner of Stockholm by conservative treatment shows a maternal mortality of 10.8 per cent.

Irradiation of the Region of the Pituitary Gland in Ovarian Insufficiency.—Alfred Szenes and Josef Palugyay (*Wiener klinische Wochenschrift,* May 7, 1925) report for the most part good results in thirty-eight patients with climacteric disturbances. Two to three weeks after the last irradiation the hot flushes disappeared entirely in eight cases, were diminished in number in twenty-four cases, unaffected in three cases, and increased in three cases. A subsequent examination in twenty-five cases three months later showed a partial or complete recurrence as to the number of flushes in more than half of the cases. After the third irradiation the number of the flushes was diminished more than one half, and after the fifth irradiation more than two-thirds of that of the first irradiation.

Attacks of perspiration, which in twenty-four cases occurred in connection with the flushes previous to the treatment, disappeared or were ameliorated in sixteen cases usually only for two months. In four cases, in which perspiration did not occur before treatment, this phenomenon occurred after varying periods after irradiation. Headaches, which occurred in twenty-eight cases previous to the treatment, were more or less favorably influenced in half the cases. In two cases, previously without headaches, the latter

occurred after the irradiation, and in one case these were aggravated. The improvement in sleep in general ran parallel with the diminution of the number of flushes.

On the basis of these results the authors feel justified in recommending irradiation of the pituitary region in cases of ovarian insufficiency. They emphasize, however, the necessity of careful doses of the amount of the röntgen rays and a very careful control of the symptoms of insufficiency, as there are cases which are aggravated by the treatment. In cases that prove completely or partially refractory after the third irradiation of the pituitary region, it might be well to irradiate the thyroid glands, and then to follow this with additional irradiation of the pituitary region only after six to eight weeks but with smaller doses, or to try the application of diathermy to the region of the pituitary gland.

Experiences with Ovarian Grafts.—Perazzi (*Revue Française d'Endocrinologie,* March-April, 1925), inserted homoplastic grafts in four women, three of whom presented signs of ovarian hypofunction, and the fourth had undergone hysterectomy with ablation of the adnexa. Autoplastic grafting was also applied to fourteen women who had been subjected to complete hysterectomy and ablation. The results were satisfactory in the first instance and generally good in the second. In homoplastic grafting attention must be paid to blood affinity between the donor of the graft and its recipient.

Stimulating Effect of the X Ray on the Genital Glands.—At the twenty-third Italian Congress of Obstetrics and Gynecology, held at Naples, May 5 and 6, 1924, A. Pais reported (*Revue Française d'Endocrinologie,* March-April, 1925) his work in this line and emphasized the benefit obtained from irradiating the ovaries of amenorrheic girls and women. Menstruation reappears and the condition renders fecundation possible. The author also reports encouraging results in rejuvenation of the genital glands by means of the x ray. Radiotherapy in stimulating doses might, he thinks, be advantageously utilized for a variety of endocrine glands.

Diagnosis and Treatment of Hypoovarianism.—In a paper by K. G. Hancher and J. Rogers (*Endocrinology,* January-February, 1925) the authors express the view that very little indeed is actually known of the functions of the ovary, our best evidence respecting them being that incomplete amenorrhea is often benefitted and symptoms sometimes attendant on it ameliorated by ovarian extracts, while total amenorrhea is never so influenced. This symptomatic improvement is explained as due probably to reflex action of the invigorated ovary on the thyroid and pituitary glands. The local pain of dysmenorrhea seems dependent on defective ovarian nutrition, and hypofunctioning is therefore presumable. This can be supposed to cause defective activity on the part of the pituitary or the thyroid. The reasons for combining ovarian with thyroid or pituitary feeding, therefore, are quite obvious. They seem each to reinforce what little is known of the function of the other, and practically a much better result may be obtained by a combination than by the use of ovarian feeding alone.

Spinal Anesthesia in Gynecological Operations.—Richard Mandelbaum (*Zentralblatt für Gynäkologie,* May 9, 1925) reports that his clinical experience does not allow him to recognize spinal anesthesia as a complete substitute for inhalation anesthesia. In general he found that the spinal anesthesia is borne better by old women than by the young. The indications for the latter must be more sharply defined. Patients with a hysteroneurasthenic predisposition are not at all suitable cases for spinal anesthesia, as this technic requires an absolutely healthy nervous system. Advanced age above sixty years is a positive indication because of the danger of pneumonia; also cases of pronounced cardiac and vascular disease.

Asthma and Ovarian Disturbance.—After noting that asthma has been recognized at times as definitely associated with hypothyroidism or with hyperthyroidism, F. Claude and H. Saleur (*Revue Francaise d'Endocrinologie,* March, 1925) present the report of a case of severe asthmatic crises in a girl of sixteen, occurring in connection with each menstrual epoch improved temporarily by ovarian extract, but receiving lasting benefit only on removal of a mildly inflamed appendix. At operation the ovaries were found enlarged and abnormal in appearance. No explanation of the connection between ovarian and pulmonary dysfunction is undertaken in the account.

Ruptured Tubal Pregnancy and Its Treatment with Own Blood Infusions.—Erich Hempel (*Zentralblatt für Gynäkologie,* February 21, 1925) bases his operative technic in ruptured tubal pregnancy upon the use of the infusions of the patient's own blood. With this procedure hasty operation is set aside; the reinfusion of the blood is the important feature and the site of the rupture is sutured subsequently. The reasons advanced are that the exsanguinated body needs the lost blood as soon as possible and that the ruptured tube is never seen to bleed.

The operation is begun with a saline infusion, and the abdominal incision is then made. A small deep longitudinal incision is made in order to catch the main mass of blood in a lowered position of the pelvis. The edges of the peritoneum are elevated so as to prevent the escape of the blood. About 200 c. c. of blood are then taken out with a ladle, allowed to run through a layer of gauze and immediately mixed with sodium citrate and then mixed with the salt infusion. This solution must not be allowed to cool. The abdominal wound is then enlarged and the rest of the blood lying in the lower pelvis is ladled out. This procedure is aided by alternating elevation and lowering of the pelvis and by compressing the flanks. The ruptured tube is then clamped and excised at the angle of the uterus. If the woman does not desire any more children she may be sterilized by excision of the other tube. Appendectomy may be done at the same time if it can be done without too much trouble.

On Climacteric Hypertension.—The fact that many instances of socalled essential high blood pressure, occurring at the menopause, are prolonged and merge into socalled senile hypertension, while others diminish and disappear with the subsidence of other menopausal symptoms, is explained by G. Marañon (*Revue Française d'Endocrinologie,* December, 1924,) on the supposition that the same pathogenic factors which cause the menopausal symptomatology also disturb and raise vascular tonus. He believes that climacteric hypertension should be attributed in the latter group of patients to a condition of vascular hypertension dependent probably on the glandular factors which signalize this crisis, and especially on the hyperadrenalinemia which unquestionably exists in these cases. The fact that in some persons hypertension attracts no attention, while in others it is accompanied by headaches, vertigo, a subjective sensation of palpitation particularly annoying at night, noises in the ears, and other symptoms, is probably due to special condition of adaptation on the part of the individual neurocirculatory apparatus. The same holds in the hypertension of arteriosclerosis. Vincent, Livon, Villemin, Schickele, Culbertson, and others have all shown that ovarian extract has a positive hypotensive action. However, the good effects obtained in many of the author's cases he attributes not alone to this, but rather to treatment by means of a régime of dietetic, hydrotherapeutic, and hygienic measures.

Studies of the Metabolism of Women. I. Variations in the Fasting Blood Sugar Level and in Sugar Tolerance in Relation to the Menstrual Cycle.—Ruth Okey and Elda I. Robb (*Journal of Biological Chemistry,* August, 1925) performed more than three hundred determinations of blood sugar, taken before breakfast, on twenty-six normal women, covering forty-nine menstrual periods, and from these analyses they feel that there is no ground for concluding that there is a consistent cyclical variation in the fasting blood sugar level in women. The average values during menstruation were slightly higher than for the inter-menstrual period. However, there were a greater number, not only of high values, but also of low values, during the menstrual period than at any other time. Hence, it is believed that in making single determinations of blood sugar for purposes of clinical diagnosis the time of the menstrual period should be avoided if possible. The ingestion of 1.75 gm. of glucose to the kilo of body weight led in the ten cases observed not only to smaller initial increases in blood sugar, but also to a greater degree of secondary hypoglycemia during the menstrual period than at any other time of the month. The effect noted immediately before and immediately after this time is just the opposite, i.e., a lessened tolerance, while the ingestion of glucose in the intermenstrual period has an intermediate effect. This smaller increase and greater decrease in blood sugar following glucose ingestion during menstruation suggests an altered functioning of the pancreas, coincident with the time of menstruation.

An Adenomyoma of the Vesicovaginal Septum and a Supernumerary Ovary.—Leo Brady (*Bulletin of the Johns Hopkins Hospital,* April, 1925) describes a case in which an adenomyoma of the vesicouterine space was found, this being the first case in the literature in which an adenomyoma in this situation has produced symptoms. In addition to this, there was a supernumerary ovary situated on the anterior surface of the broad ligament.

Effect of Various Anesthetics upon the Strength of Uterine Contractions.—M. Pierce Rucker (*Journal of Laboratory and Clinical Medicine,* February, 1925) used a Voorhees bag placed in the cervix to study the effect of anesthetics upon the contractions of the uterus. The behavior of the uterus was found to be remarkably inconstant. It would seem that all the anesthetics studied, with the possible exception of ethylene, have a tendency to diminish the force and frequency of uterine conrtactions in proportion to the amount given. This effect is less marked with nitrous oxide-oxygen, and most marked with chloroform. Secral anesthesia with novocaine is in a class by itself. Its usual effect is to stop all contractions soon after it is administered, but the contractions return with unimpaired force before the effect of the drug wears off.

Restoration of the Ability to Conceive.—Philipp Gellert (*Zentralblatt für Gynäkologie,* January 31, 1925) maintains that in the presence of functionating fallopian tubes and an absolutely intact ovary the implantation of the ovary in the body of the uterus, in addition to the operation on the adnexæ, is indicated. The technic is as follows:

The ovary is gently mobilized with the least possible injury to its vascular pedicle and inserted, together with the tubal pole, into the uterus, but not squeezed in. It is carefully sutured in place with thin catgut, being careful to avoid taking much of the ovary. With a very thin needle and a thin thread, the rupturing through of the suture may be avoided. The less the ovary is injured, the greater the hope of success.

Conception can occur only when the ova given off by the germinal epithelium which has been placed into the uterus can come in contact with spermatozoa. Rupture of the uterus need not be feared.

Dermatoses in Disturbances of Ovarian Function.—Paul Szegö (*Zentralblatt für Gynäkologie,* May 9, 1925) states that a relationship between the skin eruption and the disturbance of ovarian function may be assumed to exist under the following conditions:

1. If the constitution suggests a disturbance of ovarian function.
2. If the skin eruption and disease appeared simultaneously.
3. If the eruption disappears after the treatment with ovarian extract and the regulation of menstruation.
4. If the eruption disappears during the climacterium parallel with the retrogression of the symptoms of insufficiency.
5. When the eruption becomes aggravated on discontinuance of the treatment and subsequent impairment of the ovarian function.

Functional disturbance of the ovaries (pregnancy, amenorrhea after excision or roentgen treatment or without known cause, dysmenorrhea, oligomenorrhea, etc.) were found in eighty patients with various dermatoses. Improvement was usually manifest after the second or third intravenous or intramuscular injection of ovarian extract.

Value of Local Treatment in Uterine Hemorrhage.—Ernest Martin Fuss (*Zentralblatt für Gynäkologie,* February 21, 1925) draws the following conclusions as to the benefits to be expected from local treatment in uterine hemorrhage:

Those forms of disease of the uterine mucous membrane associated with hemorrhage which are of a chronic inflammatory nature are amenable to local methods of treatment, such as curettement and cauterization, and in the majority of cases are curable thereby. The same statement applies to the cases of atrophic mucosa in elderly women and of hyperplasia (polyps). However, in the cases of a general hyperplasia of the uterine mucosa and in those due to a functional disturbance of the ovaries, the local treatment is usually unsuccessful except in the histologically very slight cases; the success of local treatment in these cases is less the more pronounced the picture of the hyperplasia of the glandular mucosa and the more extensive the areas of diseased mucosa. In these cases cures can be accomplished only by influencing the disturbed function of the ovaries. This applies also to the hemorrhages of puberty and to adnexal tumors in younger women. In these cases, especially in the latter, better results are achieved with conservative measures, such as thermotherapy and baths, and occasionally also with operative procedures. The treatment of the hemorrhages of puberty is not rarely attended with difficulties and may necessitate a trial of irradiation of the spleen and the transplantation of ovaries. The hyperplasia of the uterine mucosa, often found as the cause of the bleeding in elderly women, except in the histologically very light cases, is absolutely refractory to local treatment and here the last refuge is the destruction of the ovarian tissue by roentgenotherapy.

Incidence of Glycosuria During Pregnancy.—Arthur Crook (*Lancet,* March 28, 1925) examined the urine of 548 patients during their pregnancy. He found that about thirty per cent. of these pregnant women passed sugar in the urine at some time during their pregnancy, and in about one third of all the cases and in about one half of those which were first detected before the fifth month it was of short duration, and not associated with other serious signs of disturbance of metabolism, while in those cases in which it appeared at about the twenty-eighth to the thirtieth week it is more often associated with signs of toxemia and more allied perhaps to the socalled renal diabetes, and in about ten per cent. of them it lasted till labor and afterwards.

In the small proportion in which the sugar appears in every pregnancy (1.5 per cent.) the proportion of definite toxemia is higher still (fifty per cent. at least), though the total number of these cases is perhaps too small to allow any conclusion to be reliable. In cases only first detected at a very late date (after the thirty-fourth week), just under three pe rcent. of them had sugar till labor, and afterwards; some of these cases were of the intermittent type. No special incidence of septic infection was noted in these patients. Though the glycosuria met with in pregnancy after the fifth month may have some relation to "renal diabetes" it does not seem to explain all the other cases (excluding of course true diabetes).

GASTROENTEROLOGY

Celiac Disease (Chronic Intestinal Indigestion).—Louis W. Sauer (*American Journal of Diseases of Children,* February, 1925) proposes the following rules for the care and feeding of celiac disease patients:

1. Hospital care is obligatory, if proper nursing care and cooperation cannot be obtained in the home.
2. Patients should be kept in bed until the weight exceeds by several pounds the child's maximum weight befor the illness began.
3. Extremes in room and outdoor temperatures must be avoided; the bedding and clothing should be suitable for the season of the year.
4. The simple, high protein (low carbohydrate and fat) diet advised consists of three phases: 1, concentrated protein milk exclusively; 2, protein milk with other protein foods (curds of buttermilk or of skimmed milk, buttermilk, eggs, lean meat and boiled tongue); 3, same as the second phase with the cautious addition of dextrinized starches (flour ball, patent barley flour, imperial granum, arrowroot crackers); the finely rolled zwieback or toast; ultimately, powdered spinach and sugars.
5. The number of calories must be ample to insure a continuous gain in weight (from forty-five to sixty or more calories per pound in twenty-four hours). At first the number of level, packed tablespoonfuls of powdered protein milk should approximate the number of pounds the child actually weighs; then gradually to approach the theoretical number of pounds the child should weigh for his height; in much retarded infants it may be necessary ultimately to use as many tablespoonfuls as the child should weigh for his age.
6. The tolerance for carbohydrate and fat should never be overstepped; fresh cow's milk, cream, butter and meat fat must be omitted for years.
7. Anorexia, abdominal distention, diarrheal or foamy stools necessitate the omission of carbohydrates, fats, fruit, vegetable and cod liver oil; after an interval of weeks or months, they may again be cautiously added.
8. In exacerbations without apparent dietary or climatic cause, parenteral infection should be searched for, as tolerance decreases during such intercurrent diseases as pyelitis, pertussis and bronchitis.

Treatment of Mucous Colic and the Colitides with Autovaccines.—Koloman von Knorr (*Wiener klinische Wochenschrift,* April 2, 1925) draws the following conclusions regarding his results with vaccinations:

1. All of the subjective and objective symptoms of mucous colic and chronic mucous colitis are relieved by autovaccine therapy. The abnormal number of colonies of intestinal streptococci and the atypical forms of colonies of the colon bacilli present before the use of vaccinations disappear at the end of the vaccine therapy. There were neither clinical nor bacteriological reactions on the part of the organism to functional tests with carbohydrate, fat, and cellulose.

2. In ulcerating acute and chronic colitis the intestinal streptococci disappear. The colonies of colon bacilli resumed their fuchsin red color and metallic lustre on endoagar. Following the vaccine therapy there develops a disease picture similar to carbohydrate dyspepsia, which can be easily influenced by the von Noorden diet or by a simple régime rich in protein and poor in carbohydrate and without sugar. In the event of a recurrence the autovaccine therapy should be repeated, but the normal colonies of colon bacillus should be omitted in the preparation of the vaccine.

3. The good therapeutic results with the autovaccine therapy can be attributed to specific reactions, as the various heteroprotein forms of therapy showed no effect. There is a marked specificity—the autovaccine from one patient shows no therapeutic result in another.

Identity of Hematoidin and Bilirubin.—Arnold R. Rich and John H. Bumstead (*Bulletin of the Johns Hopkins Hospital,* April, 1925) obtained an unusually plentiful yield of hematoidin from the hemorrhagic fluid contained in a very large cyst of the omentum removed from a child. This contained about three litres of a dark brownish red fluid, on which a van den Bergh test showed a reading equivalent to 15 units of bilirubin, while the bilirubin content of the child's plasma was so small that a quantitative estimation was impossible. The recrystallized hematoidin was subjected to the tests and reactions for the identification of bilirubin and in each instance the hematoidin behaved precisely as did a control of gallbladder bilirubin. These facts make it appear most probable that the pigment hematoidin, which is formed from hemoglobin at the site of blood extravasation, is really bilirubin itself.

A Case of Plastic Linitis.—A. H. Aaron and J. V. Wadsworth (*Buffalo General Hospital Bulletin,* April, 1925) describe a case of socalled plastic linitis in a man thirty-one years of age, marked by pain and distress coming on immediately after eating, with vomiting of unaltered food shortly after ingestion; with normal findings in the gastric juice, absence of occult blood in the gastric contents and in the stools; and the presence of a tumor mass in the epigastrium. Roentgenographically, there was considerable narrowing of the prepyloric area with no dilatation behind it. The stomach, as observed at the first operation, was the seat of a uniform sclerosis occupying chiefly the pyloric two thirds. Its size became rapidly reduced, as seen at the third operation, and the sclerosis was found to involve practically the entire organ. The mucous membrane, as far as could be determined at operation as well as at the examination of the resected portion, was intact. Histologically, the stomach showed extreme fibrosis affecting all the coats, especially the submucosa, and the presence in places of peculiar large cells which were identified with degenerated epithelial cells representing a carcinoma. From a review of the literature there appears to be no definite proof of the existence of a true linitis in the sense of Andral, Cruveilheir, and Brinton.

Argentaffine Tumors of the Appendix and Small Intestine.—Wiley D. Forbus (*Bulletin of the Johns Hopkins Hospital,* August, 1925) reviews the literature of carcinoma or carcinoids of the gastrointestinal tract, and presents six cases of socalled carcinoma of the appendix and small intestine. The argentaffine or chromaffine character of the cells of the tumors, originally described by Gosset and Masson, is confirmed. The carcinomas or carcinoids of the appendix and small intestine have their origin in the cells of Kultschitzky and Schmidt of the crypts of Lieberkühn and threfore are tumors of the chromaffine system, and may be spoken of as argentaffine tumors because of the peculiar ability of the granules of the tumor cells to reduce an ammoniacal solution of silver. The importance of differentiation between the argentaffine tumors and a peculiar form of adenocarcinoma of the appendix and small intestine, which is superficially similar to the argentaffine tumors, is emphasized. The tumors may be single or multiple, never produce symptoms or signs, and are of generally harmless character. In the author's six cases, three were found at autopsy and three at operation because of symptoms pointing to an inflammatory condition of the appendix.

Foreign Bodies in the Abdomen.—P. R. Rowlands (*Clinical Journal,* February 18, 1925) says that when a foreign body is suspected and the wound is opened up freely and explored, the body can generally be recognized by sight or touch, and can be removed, as a rule, without causing any damage. Sometimes it lies in a cavity among coils of intestine, but it may be partly in and partly outside the bowel. Whenever practicable the opening in the bowel should be closed, but this is not always possible. It is then better to drain the wound with a temporary fecal fistula, which generally closes. Failing this, the fistula may be closed by a subsequent operation, care being taken that no obstruction exists below. Drainage of the parietal wound is nearly always necessary on account of suppuration around the foreign body.

The Misuse of Cathartics and Laxatives.—John W. Dewis (*Boston Medical and Surgical Journal,* July 23, 1925) expresses the essence of his paper in one sentence which deserves to be printed in capital letters: It is dangerous to prescribe cathartics in acute or painful conditions of the abdomen; it is wrong to administer them before abdominal operations; it is injurious habitually to give them in constipation; and bad practice to order purgatives without knowledge of their various physiological effects, or to recommend them for patients when not sure of the ailment.

Diuretic Action of Bile.—A. Landau and J. Held (*Presse médicale,* March 14, 1925) noted accidentally that in some cases of edema of renal origin, the output of urine was greatly increased upon oral administration of bile, with the result that previously refractory edema was dispelled. Their experience now comprises eight cases of edema in glomerulonephritis or nephrosis and three cases of edema of cardiac origin. In the renal cases the output of urine was sometimes increased four or five times. The dose is one gram of bile four times a day in cachets or capsules after meals. Where it is desired to prevent undue diarrhea, bismuth subcarbonate or subnitrate, or tannalbin, in doses of 0.25 to 0.75 gram several times a day, according to effect, is given. The diuretic effect is ascribed to the lymphagogue action of bile. Asher observed increased flow in the thoracic duct upon intravenous injection of sodium glycocholate and of hemaglobin, while they were acting as cholagogues. This lymphagogue effect leads to a temporary dilution of the blood at the expense of the tissue fluids.

The Extrahepatic Formation of Bile Pigment.—Arnold Rich Rice (*Bulletin of the Johns Hopkins Hospital,* April, 1925) report experiments which confirm the demonstration of Mann, Bollman and Magath that the formation of bilirubin can proceed in the complete absence of the liver and all the other abdominal organs from a dog, if the circulation be maintained through the entire musculoskeletal system, the plasma, which immediately after the operation is colorless and contains no detectable trace of bile pigment, may become yellow in color after some hours and give a positive test for bilirubin; that the bilirubin may increase gradually in amount in the plasma, and that a definite tissue jaundice may develop after the lapse of sufficient time.

The Redundant Colon.—Franklin W. White (*Medical Clinics of North America,* March, 1925) states that in the treatment of redundant colon the bowel must be treated kindly and let alone as far possible; the patient rarely sees this, and has usually "beaten them up" with a long course of laxatives and cathartics, which have only added to the irritation and spasm, and often made matters worse. A bulky diet is essential, giving plenty of cooked fruit pulp and mashed vegetables, which are often better than coarser food, such as bran and raw vegetables, when there is much irritation of the bowel. Instead of irritating cathartics, we should lubricate the bowel from above and below by mineral oil by mouth and injections of six ounces of oil at bedtime, which are retained, if possible, overnight. Enemas should be avoided if possible, and only occasionally should there be used bland enemas of bicarbonate of soda, two teaspoons to the quart of warm water, which is far less disturbing than the usual suds enema. Rest and tonic measures are needed for the tense, nervous patients, and occasionally sedatives and belladonna.

The author found the results of such treatment to be very satisfactory in a large majority of his cases, especially those of mild and moderate grade, and even in some of the severe cases. Röntgenography teaches that we can never expect to make redundant colons anatomically normal, but we can often restore normal function and make the patient symptom free. There is always an accidental feature in these patients. Some of the worst cases with the largest and longest loops may go for long periods without chronic symptoms or an acute attack. No surgery, such as fixation of the colon or resection of loops, has been attempted by the author, as it seemed likely to make matters worse. It is possible that in a rare chronic case a resection of a long troublesome sigmoid loop might be profitably done. A twist of the sigmoid (volvulus) with serious acute obstruction requires immediate surgery.

Colon Bacillus Infection.—A. Basil Rooke (*Practitioner,* September, 1925) says that colon bacillus infection is prevalent and is the cause of a great deal of chronic ill health. The stage of invasion is usually ushered in by an acute febrile illness, but it may be insidious in its onset. The condition tends to become chronic. Relapses or re-infections are the rule rather than the exception. The majority of cases are associated with colitis. Gross lesions such as appendicitis, cholecystitis and renal infections are extremely common. Toxic manifestations, such as irregular heart action, mental depression, and derangement of the thyroid, frequently occur. Treatment must be directed towards improving the condition of the intestine, and increasing the patient's resistance. In order to prevent the disease from becoming chronic, treatment must continue for a long period after all signs and symptoms have cleared. It is as necessary for the Bacillus coli infected patient to have the urine examined from time to time as it is for the syphilitic to have repeated Wassermann tests.

Resistance of the Antirachitic Substance in Codliver Oil to Reagents.—Charles E. Bills (*Journal of Biological Chemistry,* May, 1925) presents the first of a series of experiments on the chemical examination of antirachitic substances. The antirachitic vitamine D was not affected by the influence of hydrogen dioxide, hydrogen sulphide, sulphur dioxide or formaldehyde. Nitrous fumes, however, readily destroyed its potency, and its activity was slowly destroyed by direct steam or contact with mineral acids.

Studies with Bacillus Acidophilus and Bacillus Bulgaricus. I. Preliminary Attempts at Implantation of B. Bulgaricus.—Nicholas Kopeloff and Philip Beerman (*Journal of Laboratory and Clinical Medicine,* August, 1925) administered to twelve women (seven constipated and five non-constipated) milk fermented by the same strain of Bacillus bulgaricus, giving one litre of milk a day in addition to the regular hospital diet for fifteen days. Three fecal examinations at three day intervals were made during treatment, and two after treatment. Of these twelve, only two subjects showed Bacillus bulgaricus; both of these were non-constipated to begin with. Since the bacteriological content of the milk fed was only fifty million to the c.c., the authors believe that further corroboration of the failure to implant Bacillus bulgaricus is required, when using the same dose of milk containing about two hundred million to the c.c., as is recommended in the feeding of Bacillus acidophilus.

Pyloric Stenosis of Infants.—A Statistical Analysis of Sixty Cases.—Wilburt C. Davison (*Bulletin of the Johns Hopkins Hospital,* August, 1925) presents a statistical study of sixty cases of pyloric stenosis in infants in relation to the following factors: symptoms, physical signs, sex, color, age at onset, birth order, type of onset, general condition of the patient, interval between onset and admission to the hospital, previous diet, birth weight, loss or gain in weight since birth, weight and age on admission to the hospital, and the month of onset. Thirty-two of the patients were treated medically, and twenty-eight surgically. The following conclusions are presented: The frequency of the condition was highest among white, male, first born infants of normal birth weight. The case fatality was highest among those who were not constipated, whose onset was sudden, who weighed less than seven pounds at birth and on admission, and who had lost the most weight since birth. No fatalities occurred among infants who were overweight at birth or who had gained in weight between birth and admission to the hospital. The fact that the case fatality rate was slightly higher in the surgical than in the medical group is no reason that all infants with pyloric stenosis should be treated medically, but it is a good argument against operating on all these patients as soon as the diagnosis is made, as some surgeons have maintained. The following recommendations are made: to operate on all patients who are in such bad condition on admission to the hospital that delay would be fatal; to try medical therapy where the condition is not critical, and to operate on patients in whom medical therapy is not producing any improvement. By such selective therapy, rather than by exclusively surgical or medical treatment, the total case fatality rate can be lowered.

Habitual Vomiting in Infancy.—H. C. Cameron (*British Medical Journal,* May 9, 1925) states that for a time to distract the infant's attention seldom fails, but always to carry the infant around after meals or to arouse its interest by means of rattles or musical boxes is apt ultimately to exhaust both nurse and child. The simple method of plugging the nostrils has sometimes achieved success. It is further recommended that the infant should always be placed upon the abdomen after a meal. Others have endeavored to prevent rumination by forcible closure of the mouth. Probably the most uniform success has been achieved by thickening the child's food to a consistency of a thick gruel.

Rumination, like aerophagy, like the vomiting due to idiosyncrasy for cow's milk, and like the vomiting of unrest, is found most commonly among infants of psychopathic inheritance and in a psychopathic environment. Isolation, handling by a competent selfconfident nurse, the reduction of emotional disturbance to a minimum, are all of the greatest importance if recovery is to follow.

Gastric Function in Health and Disease.—John A. Ryle (*Lancet,* March 28, April 4 and 11, 1925) recapitulates as follows:

There are two main types of dyspeptic reaction—the immediate and the delayed (or those associated with a recently filled or an emptying stomach). The causal or provocative factors are also of two main types, the pressor and the depressor. The dyspeptic reactions are determined in part by these causal factors, but in part also by the physiological type or gastric habitus of the individual, and the gastric habitus again (when variant from the normal) is of two main types, the hypersthenic and the hyposthenic.

Immediate pain or discomfort is the common response with the hyposthenic habitus and in dyspepsias resulting from depressor influences. It is thus encountered more frequently in the female sex and in association with general debilitating diseases. It may also be encountered in the irritative dyspepsias if these develop in a patient with the hyposthenic habitus or with general debility; under such circumstances the syndrome of gastric ulcer may be reproduced.

Delayed pain or discomfort is the common response with the hypersthenic habitus or in dyspepsias resulting from pressor influences. It is thus encountered more frequently in the male sex and in association with central or reflex irritative causes. If any of these causes are present in association with the hypersthenic habitus the symptoms of duodenal ulcer may be reproduced. The more circumscribed the focus of irritation and the more nearly it is situated to the stomach the more sharply defined do the symptoms become, but even in a "worry" or a "fatigue" dyspepsia we can sometimes detect the character of the ulcer syndrome. If an irritative focus is developed in association with the normal habitus, which is present in from seventy to eighty per cent. of the population, the liability to dyspeptic symptoms is less than in the extreme physiological types and local symptoms are more in evidence.

Finally, whether we are concerned with clinical symptoms, such as pain or nausea, or with radiological or chemical symptoms, such as hypertonus, hypotonus, hyperchlorhydria, or hypochlorhydria, it is important to appreciate that each response expresses merely an exaggeration or depression of a normal reflex. The dyspeptic reaction cannot of itself inform us as to the exact nature of the underlying disease, any more than dyspnea or tachycardia can inform us as to the exact physical condition of the heart or the causes disturbing its function. Nevertheless an estimate of the nature and degree of the functional derangement is essential both for the diagnosis and prognosis, and may materially influence the choice of treatment.

Drainage of the Thoracic Duct in Experimental Peritonitis.—Bernhard Steinberg (*Journal of Experimental Medicine,* July, 1925) undertook these investigations to determine whether or not an animal with an experimentally produced and ordinarily fatal peritonitis can be kept alive by the drainage of the thoracic duct; and whether or not bacteria are transported through the thoracic duct into the general circulation. The method of Jappelli and Lee, somewhat modified, in which the innominate, subclavian and internal jugular veins are ligated was used to secure a continuous flow of lymph from the thoracic duct. For the induction of peritonitis gum tragacanth and Bacillus coli were injected. Drainage of the thoracic duct did not save animals from peritonitis otherwise fatal. Under the conditions of the experiments the thoracic duct did not serve in any important way as a drainage tract for bacterial contamination of the peritoneal cavity.

Treatment of Pyloric Stenosis in the Infant.—Leon Velasco Blanco (*Archivos Americanos de Medicina,* July, 1925) in reporting three cases of pyloric stenosis in early infancy remarks that this is a rare condition in South America, and thinks that racial factors may be involved. Duodenal catheterization, as advised by Hess with intestinal feeding through the catheter, is the treatment of preference even in the severe cases. With this treatment the majority of cases are cured without operation, and no surgical procedure should be undertaken until Hess' method has had a fair trial. When an operation must be done the best results are obtained by the Fredet-Rammstedt method.

Antiscorbutic Properties of Eggs.—Sigfred M. Hauge and Carey W. Carrick (*Journal of Biological Chemistry,* May, 1925) state that egg whites fed to guineapigs in quantities as large as twenty c.c. daily delayed the symptoms of scurvy no longer than did the basal ration. Egg yolk proved equally ineffective when given at the rate of fifteen c.c. daily. The therapeutic action of egg portions was also negative. Therefore the presence of the antiscorbutic properties in eggs of hens is not demonstrated by these experiments, and the statement of McCollum that "egg yolk is at least comparatively rich . . . . in water soluble vitamine C" is not supported by this work.

Effect of Constipation and Catharsis on Urobilinuria.—R. S. Dean (*Journal of Laboratory and Clinical Medicine,* June, 1925) found an increase in urobilinuria during constipation, and a decrease with catharsis. A case of cirrhosis of the liver proved the only exception to this rule. From several of the cases studied, the presence or absence of fever had a decided effect on the urobilinuria.

NEUROPSYCHIATRY

Babinski or Extensor Form of Plantar Response in Toxic States Apart from Organic Disease of the Pyramidal Tract System.—T. R. Elliott and F. M. R. Walshe (*Lancet,* January 10, 1925) summarize their findings as follows:

1. An extensor plantar response characterizes the toxic state of coma without epileptiform fits (cholemia) that may arise when the metabolic functions of the liver are seriously impaired by acute or chronic diseases of that organ.
2. An extensor response does not occur in diabetic coma, nor in uremia except when the latter is associated with epileptiform fits. It has been seen in eclampsia wtih fits.
3. Delayed chloroform poisoning, sulphonal poisoning, and coal gas poisoning may all lead to the appearance of an extensor response in the absence of any organic lesion of the pyramidal tract.
4. Scopolamine will convert a flexor response into an extensor type in cases where the pyramidal tract system is only slightly affected and the drug may therefore be used to unmask a latent or equivocal extensor reflex.

Diagnosis of Incipient Insanity in Young Adults.—H. S. Le Marquand (*Lancet,* March 7, 1925) confines himself in his remarks to the diagnosis of dementia precox because it is a disease usually seen first by the general practitioner and because it is not always recognized by him.

Dementia precox is a common mental disorder in young adults. Following an insidious onset, it runs a prolonged course. The patient exhibits an inability to grapple with his environment, a consequent turning away from reality to live in a phantasy world of his own, with a progressive terioration affecting primarily his emotions and ultimately his intellect in addition. This insidious onset causes considerable difficulty to an early diagnosis because the condition is liable to be mistaken for one of the common neuroses. The diagnosis between dementia precox and these conditions is important because: 1, the different prognosis and treatment in the two cases; 2, the desirability of early investigation of dementia precox; 3, the probability of extension of facilities for treating early cases.

The diagnosis of dementia precox mainly rests on; 1, considering carefully the history of the case with the development of the personality of the patient; 2, the recognition of the typical mental symptoms and physical signs, the most typical of which are the emotional apathy, loss of energy and poor circulation in the extremities.

Difficulties in the Diagnosis of the Acute Phase of Epidemic Encephalitis in Children.—James L. Halliday (*Lancet,* April 11, 1925) states that in children the diseases most liable to be confused with early encephalitis are: gastroenteritis, tuberculous meningitis, and pneumonia. Examination of the cerebrospinal fluid will always exclude meningitis, and in certain cases will establish a diagnosis of encephalitis. In gastroenteritis the gastrointestinal symptoms are often overlooked on account of others suggesting a disease of the nervous system, such as headache, delirium, drowsiness, sighing respirations, and pseudoptosis. Pneumonia in its early stages before the development of physical signs in the chest may be mistaken for encephalitis when it is ushered in by convulsions, twitchings, delirium, meningism, drowsiness, vomiting, and pain in the side. On the other hand, pain in the side, a cough and rapid respirations may be the first symptoms of encephalitis.

Multiple Osteomyelitis Due to Bacillus Paratyphosus B.—George L. Carrington, and Wilbur C. Davison (*Bulletin of the Johns Hopkins Hospital,* June, 1925) report the case of a colored boy eight years old admitted with a temperature of 100°, rising to 106° seven hours later, with a definitely enlarged spleen and liver, and slightly swollen and tender right elbow and lower end of right humerus. Because of the enlarged spleen and possibility of malaria, a preparation of fresh blood was examined and two actively motile bacilli were seen. A blood culture made immediately thereafter showed bacillus paratyphosus B. The case is reported because of the unusual microscopic observation of motile bacilli in fresh blood preparations, and because of the rarity of such extensive osteomyelitis due to infection by bacillus paratyphosus B which involved the right humerus, radius and ulna, both fibulae, the left ulna, and scapula, and the third to ninth ribs on both sides at intervals during a period of two months.

Malarial Treatment of General Paralysis.—G. Marinesco and S. Draganesco (*Bulletin de l'Académie de médecine,* March 31, 1925) report their experiences with malaria inoculation in six cases of general paralysis, one taboparalytic case, and one case of tabes with amaurosis. The treatment is undoubtedly of value, though its mode of action is as yet unknown. Fever doubtless plays a rôle by immobilizine the spirochetes. Jahnel found that paretics who had had fever two or three days before death showed no spirochetes in their nervous system. Leucocytosis, products of the destruction of spirochetes and antibodies formed during the treatment are factors calculated to stimulate the defensive forces of the system. The writers do not believe, however, in an actual correction of the degenerative lesions of the nervous system. This is confirmed clinically in that even in cases cured from the viewpoint of social behavior some degree of mental deficiency persists. Tertian malaria should always be preferred to tropical malaria in this treatment, the latter sometimes causing serious symptoms. Of the malarial blood, collected during the chill two mils are given intravenously and four subcutaneously. The incubation period ranged from seven to eighteen days. In general the inoculation was well borne, although in one case jaundice appeared and necessitated arrest of the fever with quinine. In another case intense restlessness and mental confusion were observed during the malarial paroxysm, but disappeared as the fever subsided. Two patients had sphincter disturbances during the attack, and in the tabletic there were severe lancinating pains during the chill and even after the end of the paroxysm. An intriguing feature was the spontaneous cessation of the paroxysms. In one case the fever disappeared after the second paroxysm, and in three others, after the sixth or seventh; attempts to reproduce the paroxysms by injection of blood from malarial cases failed. In the other cases, the paroxysms were readily ended by daily administration of 1.2 grams of quinine for eight or ten days.

Section of the Sensory Root of the Trigeminal Nerve at the Pons.—Walter E. Dandy (*Bulletin of the Johns Hopkins Hospital,* February, 1925) sectioned the sensory root of the trigeminal nerve alongside the pons in two cases of tic douloureux. The approach to the nerve in this region is through the posterior cranial fossa; in all other operative procedures the sensory root is approached from the middle cranial fossa. The technic is described step by step. The advantages of this procedure are the ease of approach to the sensory root, largely due to the bloodless intracranial course; after entering the dura a free space without vascular crossings extends directly to the brain stem; the seemingly easier preservation of the motor root. Its great disadvantage would appear to be that the operation is intradural and that for this reason the effects of trauma from any undue retraction of the cerebellum and the difficulties incident to any unexpected bleeding would be serious. Whether these potential dangers prove to be actually greater than in other operations remains to be seen.

Chronic Pelvic Pain in Relation to Neurasthenia.—R. P. Ranken Lyle (*British Medical Journal,* January 17, 1925) believes that chronic pelvic pain in relation to neurasthenia is of very great importance because of the fact that large numbers of unnecessary operations have been performed for this condition, owing to the operator not recognizing the general condition of the patient and ascribing all the various symptoms complained of to some little pelvic abnormality, which could not in any way, even with the most vivid imagination, be rightfully attributed as the cause of the general condition. In other words, operations are being performed from an entirely wrong diagnosis. These operations are not only altogether devoid of danger, but they subject the patient to the risk of serious complications later on, and even at the very best they accentuate the patient's sufferings and often drive her to seek medical advice elsewhere.

Of c urse when cases of chronic pelvic pain are associated with definite physical signs, such as in pyosalpinx, there is generally no trouble in associating the pain with the physical signs, but such cases only form a small percentage of patients. The largest percentage of patients who complain of chronic pelvic pain generally have nothing abnormal in the pelvic at all, or perhaps some minor condition, such as a mobile backward displacement of the uterus, which is frequently wrongly regarded as a cause of the pain.

Often a careful examination of the pelvis and an assurance that the patient has no pelvic disease, and that the condition is merely due to worry or nervousness or constipation, will make the patient feel quite well. Other patients may require a mixture of potassium bromide and magnesium sulphate, together with fresh air and outdoor exercise, telling them not to become tired or fatigued and to stop worrying. This often is all that is required.

Contributions to the Pathology of Experimental Virus Encephalitis. I. Simon Flexner and Harold L. Amoss (*Journal of Experimental Medicine,* February, 1925) report experiments on rabbits with a virus isolated from the cerebrospinal fluid of a patient suffering from vascular and neural syphilis, who had been under continuous observation for more than two years, and who never presented symptoms of epidemic encephalitis. This virus, on the one hand, was indistinguishable from the socalled virus of encephalitis, and on the other, from the virus of febrile herpes. Twenty-seven samples of cerebrospinal fluid from cases of epidemic encephalitis were tested on rabbits with negative results. The authors propose the name "virus encephalitis" for the experimental disease produced in rabbits by the inoculation of the herpes and allied viruses.

II. In this paper Flexner and Amoss show by experiments with the H. F. virus described that the virus is markedly neurotropic and at the same time readily implantable upon the cornea and skin of the rabbit. They state that unequivocal strains of herpes virus exist in man, which, in the rabbit, exhibit a degree of encephaliticogenic power not exceeded, and perhaps rarely equalled, by any strain of the socalled encephalitis virus.

III. Varieties and Properties of the Herpes Virus.—Simon Flexner and Harold L. Amoss (*Journal of Experimental Medicine,* March, 1925) observe from a series of attempts that the detection of the true herpes virus in the buccal secretion of man is accomplished rarely and with difficulty. Their single successful instance of the isolation of a strain of the virus was obtained by the intratracheal method, which is suggested for such studies rather than that of intracorneal inoculation of the rabbit. A comparison of the Levaditi, Doerr, and Goodpasture strains of virus shows the first to be of medium, the second of mild, and the third of a high degree of neurotropic activity. The Doerr strain resembles the mild herpes strains described in this paper. Comparison of the clinical types of encephalitis in the epidemic form in man, and the experimental virus variety in rabbits brings out certain similarities and certain differences. It is only in partial and essentially superficial aspects that the two diseases can be identified with each other.

Headaches.—Henry W. Woltman (*Medical Clinics of North America,* January, 1925) states that in studying a case of headache, it is important to obtain a careful history. Seven points, at least, should be ascertained: 1, location of pain; 2, duration; 3, frequency; 4, character; 5, intensity; 6, course; 7, associated symptoms and relation to other functions.

Careful and complete examination is indicated. It should be determined, if possible, whether the headache is the expression of: 1, organic disease involving structures of the head; in this connection the aid of the ophthalmoscope should never be neglected; if brain tumor is a possibility, the pulse should be noted carefully for slowing in rate and irregularity, and the occurrence of precipitate vomiting inquired into; the organs of special sense call for investigation, and the skull should be palpated, and an x ray examination made; 2, toxic factors, especially nephritis; 3, circulatory disturbances, especially hypertension; 4, migraine and its variations; here we are dealing with the patient rather than with the cause; 5, psychoses, psychoneuroses, neurasthenia, and exhaustion; the emotional behavior and daily habits of the patient should be ascertained; and 6, neuralgias; not every pain is neuralgia.

Combinations of the foregoing conditions are possible. In certain cases the patient may require observation for a prolonged period before a diagnosis can be definitely established.

Influence of Sexual Developmental Stages and Processes on Otosclerosis.—Conrad Stein (*Wiener klinische Wochenschrift,* January 29, 1925) concludes that when physiological and pathological processes of the genital apparatus develop in an individual predisposed to generally degenerative changes, in whom the auditory apparatus is also constitutionally insufficient, an injury of this auditory apparatus should always be suspected. The possibility of such an endogenic involvement is seen from the fact that within the picture of such a status degenativus the whole series of organs and apparatus, which ought to enhance the normal structure and functional power of the auditory apparatus, are functionally or organically involved as parts of this pathological condition.

The author emphasizes the predominant involvement of the female sex, the influence of menstrual disturbances, of pregnancy and the climacterium and the course of the disease. In males, the significance of sexual neurasthenia, and in both sexes the influence of abnormal sexual life deserve special mention. Constitutional insufficiency, neuropathy and disturbances of internal secretion are found in various combinations with otosclerosis. Therefore, the treatment must be arranged in accordance with the conditions found in each case, and strict individualization is always indicated.

Ophthalmological Findings in Cases of Multiple Sclerosis.—John F. Gipner (*Medical Clinics of North America,* January, 1925) states that in multiple scelrosis, changes in the optic nerve are often early objective signs of the disease. About fifty per cent. of the cases show changes in the disc, the most frequent change observed being a generalized pallor of the disc without loss of nerve substance. Simple optic atrophy, definite temporal pallor, and questionable temporal pallor are infrequent findings, each occurring in about the same proportion of cases. Disproportionality between the appearance of the fundus and the central and peripheral visual acuity is characteristic of multiple sclerosis. The generalized pallor of the discs may confuse this condition with tabetic atrophy, and the cases with acute retrobulbar neuritis present the same picture as those in which there is toxic neuritis due to alcohol, tobacco, and accessory sinus disease.

Medicolegal Notes.

Father's Liability for Physician's Services to Adult Daughter

An action by a physician for services to defendant's daughter presented the question of whether the parent is liable for necessaries furnished his adult daughter, living in his home as a member of his family, at a time when she is sick and unable to earn a living. The daughter was about twenty-three years of age, but had never had employment or earned her living. She was under the physician's care about eight months, six weeks of which she spent in a hospital. She and her father were not on friendly terms, never speaking to each other except when absolutely necessary. The mother was also estranged from the father, although they lived in the same house.

The mother and daughter went to the doctor's office when his services were engaged. Nothing was said as to who would pay the bill. The doctor never went to the parental home, and the father never knew of the doctor's employment until long after most of his services had been rendered. He did not authorize or direct his daughter or wife to engage the physician or consent to his engagement, or promise or agree, directly or indirectly, to pay for the services.

From the authorities cited by the parties, the Kentucky Court of Appeals, Breuer v. Dowden, 268 S. W. 541, deduced the rule to be that "a parent is not liable for the debts of his adult child in the absence of a statute to the contrary, unless the child in such a feeble and dependent condition physically or mentally as to be incapable of supporting himself; that if at the time the child becomes of age he is physically and mentally sound and able, if willing, to make and earn his own support, the parent is not liable for his debts or obligations thereafter contracted, even though he should later become sick or mentally unbalanced and therefore incapacitated to earn a livelihood. If, however, the child at the time of his arrival at the age of twenty-one is sick or otherwise incapacitated to earn a living for himself, and is, at the time, living in the home of the parent as a member of the household, the parent is liable for the necessaries furnished him."

"If it appeared," the court said, "from the evidence in this case that the adult daughter of appellant who lived in the home as a member of the family was physically or mentally incapacitated to earn her own livelihood at the time she arrived at her majority, and that this disability continued until the employment of appellee physician, we think his cause would be maintainable, but in the absence of such a showing we must hold that the father's liability for the debts of his adult daughter, even for necessities, terminated on her arrival at the age of twenty-one years, and having once terminated cannot be revived even though she became sick and incapacitated while continuing as a member of his household.

"It must not be overlooked that the physician was engaged by the daughter without the knowledge or consent of the father, and that the first bill he rendered for services was made out and forwarded to her. When received by the daughter she immediately, without consulting her father, called at the physician's office and told him that she had nothing with which to pay him, and that she expected her father to pay the bill for her. Thereupon the physician mailed the bill to the father and requested payment. These facts make it certain that the services were rendered to the daughter upon her credit, and that credit was not extended to the father.

"We are also of opinion that the mother had no authority as agent of the father, under the facts of this case, to engage the physician to perform services for her adult daughter, if indeed she did attempt to make such engagement."

For these reasons judgment for the plaintiff was reversed.

Expert Opinion Based on Statements as to Subjective Conditions Held Incompetent

In a personal injury action the Kentucky Court of Appeals held, Illinois Central R. Co. v. Townsend, 267 S. W., 161, that expert medical testimony as to plaintiff's injuries, consisting wholly of opinion based, not on objective symptoms, but on statements made by the plaintiff on examination by the physicians, not for treatment, but for the purpose of testifying at the trial, was incompetent.

It was also held that a question to such medical witness whether the subjective conditions be found could have resulted "from sudden shock or the application of force to the body," was improper, when under the evidence, the occurrence of a sudden shock was problematical, and there was no direct proof that any force had been applied to plaintiff's body. The proper question, the court said, would have been to have incorporated the facts as to how the collision occurred, as testified by the plaintiff, and have the witness give his opinion based upon these facts.

A question based upon the assumption that plaintiff's injury, whatever produced it, produced the conditions discovered by the witness was also held improper. The question should have been based upon the testified facts as to how the collision occurred, and then inquired of the witness whether such facts could have produced the conditions, and whether they were or were not permanent.

X Ray in Case of Fractured Hip

The California District Court of Appeals, Second District, holds, Pearson v. Crabtree, 232 Pac., 715, that an x ray specialist, in the treatment of a fractured hip by the use of the x ray, was only required to use such reasonable care, skill and diligence as are usually or customarily exercised by others in the same line of practice and work in similar localities, or in the same section of the country; and that the testimony showed that it is not customary in the case of a fractured hip to take pictures of both hips unless something arises to make it necessary, and that it is not done in all cases.

Assessment on Cities for County Tuberculosis Hospital

By Massachusetts St. 1924, c. 443, Newburyport, together with four other municipalities, was included within the Essex County tuberculosis hospital district and rendered liable to assessments therefor. The Massachusetts Supreme Judicial Court holds, County Commissioners v. Mayor of Newburyport, 147 N. E., 901, that the statute confers upon the county the right of action by contract to recover the assessment imposed upon the city by Sec. 3 as its proportion of the initial cost of construction of the hospital.

Disease Held Not Shown to Be Result of Accidental Injury

The Indiana Appellate Court, U. S. S. Lead Refinery v. Devetak, 147 N. E., 926, reversed an award of compensation by the Industrial Board, where claimant's own witnesses, medical experts, described his ailment as a disease, eczema, and were enable to say that it resulted from the conditions of his employment; the court holding that the board was not justified in finding that the claimant was entitled to compensation because of an accidental injury received in the course of his employment.

Proteins and Human Metabolism

WILLIAM HENRY PORTER, M.D.
New York

Proteins in conjunction with water and the mineral salts are the constructive agents constituting animal life.

During intrauterine life every element entering into the construction and maintenance of the embryo is derived directly from the animal kingdom. The proteins after birth are obtained from both the animal and vegetable kingdoms, but directly after birth, entirely from the animal. Proteins derived from the animal kingdom are the most easily assimilable into the human body tissues. Those coming from the vegetable kingdom are more difficult to assimilate and in many instances a high percentage of proteins of vegetable origin can under no circumstances be converted into the human body tissues.

Therefore from a purely economical viewpoint animal proteins are the most valuable, for they are more easily digested as well as assimilated, all of which is accomplished with a very low percentage of loss from the total amount ingested; the reverse is true when vegetable proteins are used. Witness a single fact when the human economy is, so to speak, dangerously ill from any cause, and without any knowledge of chemistry or physiology on the part of the general public, simple common sense, horse sense, socalled, taught people that food of animal origin, such as milk, eggs and meat broths, was the food most likely to enable Nature to effect a cure.

Another highly important fact in connection with the proteins is that some are probably the socalled vitamine principles—substances recently brought to the attention of scientists under this name and largely heralded to the world by the daily press. To my mind it is a fact that certain proteins constitute these socalled vitamines—substances which are so essential to perfect nutrition, especially since the overrefinement of most food products. These vitamine principles by this overrefinement have been withdrawn or extracted from food products. Before this superrefinement of food stuffs the animal economy received these lifegoverning principles as Nature intended, and their utility was not discovered. It is highly probable that these vitamine proteins are simply different isomeric forms of the protein molecule. That they exist in both the vegetable and animal kingdoms is unquestioned, but in such minute quantities that they have never been isolated nor their identity fully established from a purely chemical viewpoint and possibly never can be so identified. They have, however, from a physiological and nutritive viewpoint, been fully established both as to their existence and the necessity for their presence in our food products. It has further been demonstrated that it is their presence and actions that control perfect assimilation and normal growth. In these almost infinitesimal quantities they unquestionably act upon the general oxidation and assimilative processes in one of two ways. As activating or inhibitory agents, so that by this double action, as it were, they keep the chemical and physiological processes constituting animal life, in perfect harmony and equal balance under all circumstances and conditions. Deprive the system of their actions, and disease and death ensue.

From the time proteins were discovered and their functions somewhat understood, endless research work has been carried on to determine if possible a fixed amount of protein that must be supplied to the system daily to constitute and maintain the condition generally recognized as perfect health. Upon careful consideration it must be clear to all observers that no absolutely fixed quantity can be given exactly, for difference in size and construction of individuals must vary the amount of protein required.

Likewise, the physical and mental work performed must vary the demand, so that each individual becomes, as it were, a law unto himself or herself, continually changing also as the hours and days go on. General averages may be established up to a certain limit. Up to the present time, however, no extremely satisfactory result has been recorded with sufficient uniformity to be fully satisfactory.

The daily amount of protein has been placed as low as eighty grams by some observers and as high as 242 grams by others. This on the face of it is a pretty wide difference for the average development of human species. Humanity as a class does not show quite so wide a difference in construction nor in the work it accomplishes.

Such differences might be admissible if a Tom Thumb were pitted against a supergiant, but not for the average of mankind as generally observed. Therefore some correction or adjustment must be made to determine somewhat practically how much protein must be ingested daily to maintain a perfect and well balanced diet. The term well balanced diet is very freely used by many, while few fully realize

Copyright, 1925, by A. R. Elliott Publishing Company.

just what is or should be expressed by so simple a term. The expression well balanced diet covers a complex problem.

First. It is one in which the amount of food ingested must be kept, first of all, well within the oxygenating capacity of the system, be that capacity normal or abnormal.

Second. It must be one which furnishes the requisite amount of heat energy perfectly to energize the chemical and physiological activities of the animal economy.

Third. It must be one in which the requisite amount of heat energy is developed along the enterohepatic circuit, and at the same time just the right amount of heat energy along the cardiopulmonary circuit, so that perfect harmony of heat energy from these two great furnaces of the human system, as it were, is carried up to and reflected back from the cerebral and spinal system of the great nervous mechanism and will be such as automatically to keep in harmonious motion all the functions and actions of the various organs of the body.

Fourth. With the growing offspring sufficient proteid material, preferably of animal origin, must be supplied to make good the daily loss of this material and still have enough left so that additional protein elements can be accumulated within the system until growth is accomplished. Once fully grown, just enough protein must be supplied during every twenty-four hours to yield some heat energy and make good the daily loss of protein due to general wear and tear. The only manner in which this loss of protein material can be estimated is by determining the amount of nitrogen eliminated in the normal endproducts of proteid oxidation. When the reduction is perfect the individual is normal; imperfect products indicate abnormalities and degrees of abnormality. This must be done for each of every twenty-four hours.

Fifth. In conjunction with the glucose, fats and proteins, there must also and at the same time be supplied the requisite amount of water and certain inorganic elements. These inorganic or saline compounds are absolutely necessary for perfect digestion, assimilation, alkalinization, and construction and maintenance of the bones. It is quite recently that their full importance and just how they act have been explained.

Sixth. One salt, disodium monohydrogen phosphate, is absolutely essential for perfect digestion and to maintain perfect alkalinity of all the body fluids and tissues; and last, but not least of its activities is its power to fix or hold the calcium or lime elements in fixed relation to the protein substances, thus forming the perfect bones, teeth and all hard structures of the body. To emphasize this particular salt and its action it is best designated as a fixator (1). If there is an abundance of available calcium, without the right amount of this fixator, bones and hard structures can not be perfectly produced. By these varied actions this particular chemically pure salt is one of the great inorganic regulating elements in connection with perfect oxidation and reduction of all oxidizable substances introduced into the body. One thing especially must be remembered: that no other alkaline substance can be substituted for this particular preparation. This inorganic fixator, like the vitamines of the organic kingdom, might be classed as the inorganic element, aside from water, most essential to perfect metabolism and growth. When all the above conditions have been completely met we are justified in using the term perfect and well balanced diet. The object of dieting is not to starve or fatten, but to arrange all the above ingredients in such manner as to secure the most perfect result, both in health and disease.

In the light of this great and complex problem, yet one which is perfectly simple when fully understood, to estimate nutritive standards by calories is too absurd for further consideration. The calorie is a register of heat energy only, the nitrogenous endproducts register both normal and abnormal metabolism, perfect endproducts indicating normal conditions, imperfect ones abnormal states. Both can be easily and practically determined (2).

If for any reason the system has become more or less abnormal, theoretically a perfect adjustment in the diet should bring about perfect normal conditions. Oftentimes, however, diet alone will not produce the desired result. Scientifically applied medication will almost invariably cause a return by nature to complete and perfect normal standards, except in a few instances commonly classed as incurable; all of which, in the light of our everadvancing knowledge, will be pushed over into the curable class. Every abnormal condition, therefore, can be made perfect by scientific dieting and medication.

Medicines, no matter how well selected, can never cure any diseased condition. They all act in one way, the same as borrowed capital does in the financial world, by enabling the enfeebled or broken system more fully to utilize the well balanced diet, when Nature unaided by this borrowed capital medicine could never repair the damage no matter how perfectly the well balanced diet was adjusted.

It is in the use of medicines as here outlined that therapeutics becomes a true science and of absolute practical value to suffering humanity. It further proves that nihilism in therapeutics is wrong and a crime against suffering humanity.

With these facts before us it becomes more simple to demonstrate practically what to expect where certain quantities of the proteins are introduced into the human system in conjunction with glucose and fats, that is, assuming that they are perfectly utilized, as they must be to bring about perfect and normal conditions.

We can determine also with a high degree of probability about how much protein is required daily to produce a fully developed human body and how much is required to maintain this perfect state of development.

Some years ago I (2), in an attempt to determine what in all probability might be regarded as the rightful amount of nitrogen to be eliminated daily by the average normal human individual, secured as many recorded urine analyses of apparently normal persons living in all parts of the world as could be collected, eliminated all analyses that indicated diseased conditions or very wide ranges in composition, added them all together and divided by the number taken.

This furnished a good working basis for further studies so far as the elimination of nitrogen from the

system through the urine and other channels was concerned. As only a part of the nitrogen eliminated from the system escapes with the urine, similar estimates had to be made for all secretions and excretions carrying nitrogen out of the system, as the sweat, bile, and other substances. The total amount of nitrogen eliminated daily by all these various channels was found to be in round numbers twenty-four grams when the system is performing a full average day's work.

This total elimination of nitrogen is considerably larger than is generally given when it is assumed that practically all the nitrogen escapes with the urine, while the actual fact is that only seventy-three per cent. of the total nitrogen escaping from the body departs by the urinary channel and only sixty-eight per cent. as urea. To compute results as so many have done, by assuming that all the nitrogen eliminated is to be found in the urine, results in an error of twenty-seven per cent. at the very start. Or to be absolutely accurate twenty-three per cent. If based on urea alone the error is thirty-two per cent. Most observers admit the possibility of five per cent. of nitrogen escaping by some other channel than the urine. But an error of twenty-three per cent. is far too great to start any practical deductions from. With all these facts established it is quite easy to analyze and compute the results to be obtained from all forms of diet composed of the three oxidizable substances, glucose, fats and proteins, no matter what the proportions are. These are facts that every one should know thoroughly before advising patients as to what is best to eat. And it should always be remembered in every instance each individual is largely a law unto himself. In McKendricks (3) *Physiology* satisfactory computations are recorded relative to the amount of heat energy required to sustain the perfect chemical and physiological activities of the human economy. His estimates were originally given in foot pounds, which translated into large calories call for a maximum of two thousand five hundred calories daily as an average. This, too, like the amount of proteins consumed must be augmented two or three times more for the simple heat producers than for the proteins with increased work, which can be done with perfect safety up to a certain point, that is, kept within the safety limit. The proteins likewise must be increased to accomplish more work, not in equal proportion to the augmentation of simple heat producers, for heat energy must be greatly augmented to produce superwork. Hence, the danger of imperfect oxidation. At one time as the result of incorrect observations it was thought increased work was accomplished by the utilization of less protein material.

This error crept in when Professor Dalton made a close observation of the nitrogen eliminated by Weston when the first famous six day walk was made in old Madison Square Garden. Dalton studied the nitrogen elimination in the urea only, overlooking the fact that increased work calls for a tremendous augmentation in heat energy to produce the increased work. That this in turn soon overtaxes the oxygenating capacity of the system, followed by imperfect oxidation reduction of protein bodies, is evidenced by a steady decrease in urea elimination and a proportionate or greater output of uric acid. As each molecule of uric acid carries twice as much nitrogen as does the urea molecule, the nitrogen elimination must be computed both in the urea and uric acid, in fact in all nitrogen carrying bodies eliminated. When this is done it proves conclusively that increased work calls for the utilization of more protein and a consequent increase in the nitrogen elimination. It must be remembered also that protein is a heat producing food as well as a constructive agent. The protein, as Professor Lusk (4) states, "has one property out of all proportion to that possessed by other food stuffs; it very largely increases the production of heat in the body, apparently acting as a chemical stimulus and not alone by virtue of its heat energy content." In brief, as Lusk states it, "protein is necessary to maintain tissue repair, to promote growth, and that when taken above the requirements for these purposes it stimulates the organism to a higher level of heat production."

The dominant idea under all circumstances is to keep the food intake always under the oxygenating capacity of the system. This applies absolutely to the protein elements, for it is out of the incomplete and imperfect oxidation of proteins that we derive all kinds and every form of abnormality and disease, extending from the slightest functional disorder to actual disease and death.

With all these data before us we can in a comparative manner analyze the various diets that have been recommended by various dietitians. In building up diets certain facts must always be remembered. All should contain the three oxidizable elements, glucose, fats and proteins. Whatever the diet, it must always be remembered, no matter what the condition of the system is, that it must be kept well within the oxygenating capacity. Taking 750 grams of oxygen for the normal daily intaking capacity of the average system for oxygen, we can on this basis proceed to analyze diets.

Food taken up to this point is within the safety line, beyond this point we pass into the danger zone. We then pass to a functional or organic disease and on to death as the case may be.

Many conditions vary the intaking capacity of the system for oxygen, all of which must be considered in planning a diet, which must always keep within the oxygenating capacity. Failure to meet these requirements results in no improvement in the patient and he passes from bad to worse and not infrequently to death.

MC CANN'S IDEA OF DIET, OR DIET NO. 1

In this arrangement the amount of protein material needed daily is the lowest of all. Hence we will consider it and its result first.

Protein	80 grams	yielding	326 heat units
Fat	84 grams	yielding	761 heat units
Glucose	271 grams	yielding	1017 heat units
Total	435 grams	yielding	2104 heat units

Grams of oxygen required to burn 80 gms. of protein	110.668
Grams of oxygen required to burn 84 gms. of fat	243.797
Grams of oxygen required to burn 271 gms. of glucose	289.048
Total.....	643.513

The maximum yield of nitrogen from 80 grams of protein is 14.40 grams, sixty-eight per cent. or 6.79 grams of which is excreted as urea or 14.20 grams of urea.

With this type of diet we do not secure the normal maximum heat energy production. We are still 106.487 grams of oxygen within the safety limit, so that more heat producing food could easily be added. Note, however, the very low urea output. With such a low output of urea most examiners of urine would suspect some abnormal or diseased condition. Yet according to the promulgator of this diet it indicates a normal state of the system, and all the protein material needed.

The next lowest diet in protein, glucose, and fat was designated by its promulgator as:

A BARE SUBSISTENCE DIET. DIET NO. 2

Protein	100 grams	yielding	410 heat units
Fats	45 grams	yielding	418 heat units
Glucose	55 grams	yielding	206 heat units
Total	200 grams	or a total	1,034 heat units

Gms. of oxygen required to burn	100 gms. of protein	137.966
Gms. of oxygen required to burn	45 gms. of fats	130.603
Gms. of oxygen required to burn	55 gms. of glucose	58.663
Total.....		327.232

The maximum yield of nitrogen with a diet of this composition will be eighteen grams, sixty-eight per cent. or 12.24 grams of which is excreted as urea or 29.42 grams of urea. The saving of oxygen on a diet of this composition is enormous, less than one half the normal maximum intake being used, or 412.768 grams less than the normal capacity, which would be in comparison like having only half the number of red oxygen carrying corpuscles or one half the hemoglobin.

While this diet contains more protein elements than McCann's, it is a question if there is sufficient heat energy developed to energize the system sufficiently to oxidize perfectly the larger amount of protein material; it certainly is a bare subsistence diet from a calorie viewpoint. Such a diet might be used to reduce fat or to offset the nontoleration carbohydrate theory of diabetes. It is a diet more likely to produce than to cure abnormal conditions, being too much out of proportion.

RANKIN'S DIET OR DIET NO. 3

Protein	100 grams	yielding	410 heat units
Fats	100 grams	yielding	930 heat units
Glucose	240 grams	yielding	901 heat units
Total	440 grams	Total	2,241 heat units

Gms. of oxygen required to burn	100 gms. of protein	137.966
Gms. of oxygen required to burn	100 gms. of fats	290.230
Gms. of oxygen required to burn	240 gms. of glucose	217.056
Total.....		645.252

The maximum yield of nitrogen with a diet of this composition is the same as in a bare subsistence diet, eighteen grams, sixty-eight per cent. or 12.24 grams of which is excreted as urea or 29.42 grams of urea.

In this diet we have a much larger heat energy development and a greater possibility for perfect oxidation of the protein elements. In fact it is a fairly rational diet, keeping within the oxygenating capacity of the system by 4.748 grams under the safety limit. Still, full heat energy has not been developed. The nitrogen output remains low, the heat energy under the 2,500 calorie standard. Hence it is not a perfect balanced diet, so far as the three oxidizable food elements are concerned. The maximum yield of nitrogen is eighteen grams, sixty-eight per cent. or 12.24 grams of which is excreted as urea or 29.42 grams of urea.

The following diets have been given under the following captions:

FOR MODERATE EXERCISE OR DIET NO. 4

Protein	180 grams	yielding	738 heat units
Fat	72 grams	yielding	670 heat units
Glucose	89 grams	yielding	333 heat units
Total	341 grams	yielding	1,741 heat units

Gms. of oxygen required to burn	180 gms. of protein	152.324
Gms. of oxygen required to burn	72 gms. of fat	209.965
Gms. of oxygen required to burn	89 gms. of glucose	93.027
Total.....		455.316

The maximum yield of nitrogen in this diet is thirty-two grams, sixty-eight per cent. or 21.760 grams of which is excreted as urea, or 44.60 grams of urea.

FOR ACTIVE LABOR OR DIET NO. 5

Protein	232 grams	yielding	951 heat units
Fat	77 grams	yielding	713 heat units
Glucose	94 grams	yielding	353 heat units
Total	403 grams	yielding	2,017 heat units

Gms. of oxygen required to burn	232 gms. of protein	220.057
Gms. of oxygen required to burn	77 gms. of fats	223.477
Gms. of oxygen required to burn	94 gms. of glucose	948.274
Total....		1,391.808

The maximum yield of nitrogen from this diet is forty-one grams, sixty-eight per cent. or 27.889 of which is excreted as urea or 50.00 grams of urea.

FOR FORCED WORK OR DIET NO. 6

Protein	242 grams	yielding	992 heat units
Fat	85 grams	yielding	790 heat units
Glucose	104 grams	yielding	390 heat units
Total	431 grams	yielding	2,172 heat units

Gms. of oxygen required to burn	242 gms. of protein	333.863
Gms. of oxygen required to burn	85 gms. of fats	246.695
Gms. of oxygen required to burn	104 gms. of glucose	1109.264
Total....		1,688.822

The maximum yield of nitrogen from this diet is forty-four grams, sixty-eight per cent. or 29.920 grams of which is excreted as urea or 65.90 grams of urea.

In the three diet tables designated as for moderate exercise, active labor and forced work, the protein substances are steadily increased for increasing labor. The total nitrogen eliminated, assuming that the proteins are perfectly reduced, is far in excess of our normal standard of twenty-four grams for each and every twenty-four hours. The amount of fat and glucose is exceptionally low in all three, so much so that it is a question if there is sufficient heat energy produced with which to perform extra work and perfectly reduce the proteins to their normal end-products.

In Diet No. 4 the amount of the three oxidizable food products as here given can be completely reduced, so far as the oxygen supply is concerned. For if they are completely and perfectly reduced there will be left a surplus of 294,684 grams of oxygen within the safety limit, consequently the glucose and fat can easily be increased and thus secure the much needed heat energy to accomplish the extra work and completely reduce the proteins.

In diets five and six, those designated for active and forced work, heat energy is deficient. Here the utilization of oxygen has passed the safety limit by

many grams; hence no more heat energy can be produced and only one thing can happen. The glucose and fats will be reduced to their perfect endproducts, and some of the protein must be imperfectly oxidized or escape under its own form, unreduced, from the body, under this condition abnormal endproducts must be found in some of the secretions or excretions, if not in all, and one of these products is in the form of a glucose molecule (4) Fig. 1. In fact it is by a similar reduction of the proteins that the Eskimo secures normally his supply of animal starch (glycogen) (5) or glucose.

Therefore the diets as here outlined must damage any one who tries to live on them. The only method by which it can be made practically workable is to readjust the amount of glucose, fats and protein until the amount taken comes within the oxygenating capacity of the system or 750 grams of oxygen. This accomplished, it is another form of diet.

MOLESCHOTT DIET OR DIET NO. 7

Protein	120 grams yielding	492 heat units
Fat	90 grams yielding	837 heat units
Glucose	330 grams yielding	1,239 heat units
Total	440 grams yielding	2,568 heat units

The maximum yield of nitrogen is 21.60 grams, sixty-eight per cent. or 12.29 grams of which is excreted as urea or 32.90 grams of urea.

Gms. of oxygen required to burn 120 gms. of protein	155.552
Gms. of oxygen required to burn 90 gms. of fat	261.207
Gms. of oxygen required to burn 330 gms. of glucose	351.978
	768.737

The Moleschott diet, so far as known, is one of the first attempts to present the food elements under this arrangement and show just how much heat energy can be produced by burning glucose, fat and protein within the system. It also shows conclusively how much oxygen must be consumed if these three food elements are completely and perfectly burned. With this adjustment, heat energy and oxygen consumption are both a shade above the normal standard 2.500 heat units and 750 grams oxygen.

Remembering, however, that there is always a slight percentage of the protein lost in the digestive process, both the production of heat units and oxygen consumption will fall just within normal limits. Thus far it is a perfect diet. There are, however, two defects, the nitrogen output is below the normal twenty-four grams standard.

On the whole, however, it comes very close to being a perfect balanced diet. The one other defect is that too much heat energy is developed along the enterohepatic circuit where most of the glucose and proteins are oxidized, and too little along the cardiopulmonary circuit where the fats are oxidized.

None of the other diets here given with one exception comes anywhere near approaching its perfection.

LUSK'S DIET OR DIET NO. 8

Protein	150 grams yielding	615 heat units
Fats	110 grams yielding	1,023 heat units
Glucose	525 grams yielding	1,971 heat units
Total	785 grams yielding	3,609 heat units

The maximum yield of nitrogen is twenty-seven grams, sixty-eight per cent. or 18.36 grams of which is excreted as urea, or 41.11 grams of urea.

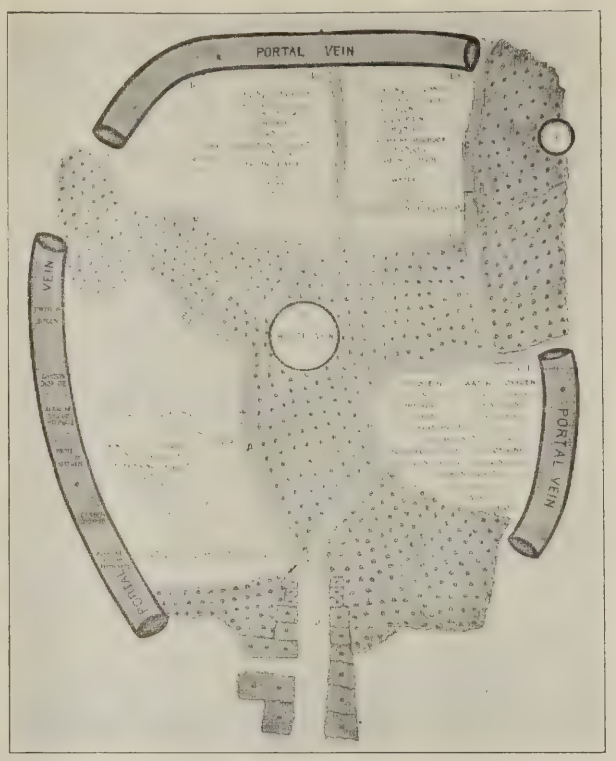

FIG. 1.—Schematic drawing illustrating how the proteid molecule is oxidized or broken up in the hepatic cells, the normal and some of the abnormal products that may be produced in the hepatic cells. (Drawn by John J. McAulliff.)

Gms. of oxygen required to burn 150 gms. of protein	206.890
Gms. of oxygen required to burn 110 gms. of fat	310.253
Gms. of oxygen required to burn 525 gms. of glucose	557.865
Total....	1,084.008

The Lusk diet contains the same amounts of protein and fats as does the Porter diet table. It is, however, much richer in glucose, so much so that if the three food elements were completely oxidized it would yield a tremendous amount of heat energy.

In this respect it is an illustration of what the farmers try to do, it being found that they are supposed to require about 3,500 calories to accomplish the work they strive to perform (4).

To oxidize all of the three classes perfectly, in the amounts as given in this table, calls for a very large expenditure of oxygen or 334 more grams than the maximum oxygenating capacity, or that much beyond the safety limit.

It fully illustrated what the New Englanders tried to do when they worked from sunrise and before, and on the other end of the day to sunset and as long after as daylight lasted.

As in all the other tables where the quantity of food ingested exceeds the safety limit in oxygenating capacity, the suboxidation falls completely upon the protein molecules. As a result various kinds of noxious products are developed, varying in the intensity of their toxicity, some causing rheumatic conditions, some chronic endocardial lesions, some fatty changes in the bloodvessels, followed by hemorrhages in the brain, true apoplexy, and other conditions. In the days when these attempts were made to increase, beyond the safety limit, the working capacity of the human economy, many at the comparative early decades of their lives were crippled if not actually

killed. These instances were frequently observed during my boyhood days when living in the country. It was not until recent years, however, that the explanation of the caustive factors and frequency of these cases became clear to me. Since the inauguration of the shorter hour day and less activity while at work this class of semicripples at comparatively early years has decreased in numbers to a considerable extent and if all could live on a perfectly balanced diet such conditions would be rarely seen.

PORTER'S IDEAL DIET OF DIET NO. 9

Protein	150 grams yielding	615 heat units
Fats	110 grams yielding	1,023 heat units
Glucose	150 grams yielding	563 heat units
Total	410 grams yielding	2,201 heat units

The maximum yield of nitrogen is 27 grams, sixty-eight per cent. or 29.92 grams of which is excreted as urea, or 41.11 grams of urea per diem.

Gms. of oxygen required to burn 150 gms. of protein	206.890
Gms. of oxygen required to burn 110 gms. of fat	319.253
Gms. of oxygen required to burn 150 gms. of glucose	142.991
Total.....	669.134

In this diet I have tried to correct the slight defects as outlined in connection with the one given by Moleshott. It is not an inherently new diet, but one rearranged after Moleshott. It contains more protein and fat and less glucose.

The protein is increased to raise the nitrogen output up to the normal twenty-four grams standard. In this instance if all the protein were absorbed and completely reduced, the nitrogen output would be in excess of the normal standard. When a percentage of ingested protein is deducted, then the nitrogen output falls pretty close to the normal twenty-four grams standard.

It keeps well within the oxygenating capacity of the system, leaving a surplus of 80.866 grams of oxygen. It is slightly under the normal heat energy standard of 2500. This defect can be easily compensated for by using the excess of oxygen to burn a little more glucose or fat, or both. This done the heat energy will be fully up to the normal standard.

The striking difference in my diet as compared with all others, is a larger amount of fat, except in the Lusk diet, and a much smaller quantity of glucose than is found in any other diet except in those that are all out of proportion.

The reason for this arrangement was to secure a more equal generation of heat between the enterohepatic circuit and the cardiopulmonary circuit. While the balance is not absolute, it closely approaches the enterohepatic heat production being 1,178 large calories and the cardiopulmonary 1,023 large calories. A slight shifting in the quantity of glucose or fat or both would make the two absolutely equal.

I have been using this modified Moleshott or the Porter (6) ideal mixed diet for more than twenty years, with highly gratifying results, both to myself and to my patients.

There is just one point in connection with the use of glucose, possibly not known to many, to wit: There are eleven isomeric glucose molecules known to chemists, one of which has been designated by Professor James C. Irvine, of Edinburgh, as a gamma glucose, or one that can be utilized by the system under the most adverse conditions. Professor Irvine has said that it is capable of curing diabetes, and is the only true curative factor for diabetes mellitus.

I have been using for several years past what I believe to be the so designated gamma glucose, and in many instances have found the glucose in the urine to disappear rapidly when the patient was placed on gamma glucose and at the same time upon a perfectly balanced diet, and given liquor calcis et sodii phosphatis compositus, with no other medication. At times, however, as previously stated in this paper, other medication is absolutely essential, as insulin, for instance, and various other pharmaceutical preparations. Insulin is a wonderful remedy for emergency work, but not for continuous and promiscuous administrations; in fact, all medication should be directed exclusively by trained and skilled medical men.

With all these facts closely in mind, it is perfectly simple to arrange a perfect and well balanced diet, that will fit all conditions, both for normal individuals and every conceivable abnormal condition as well.

Pharmacological and Therapeutic Properties of the Sulphocyanates.—John Benjamin Nichols (*American Journal of the Medical Sciences,* November, 1925) says that the therapeutic effect of sodium sulphocyanate in lowering blood pressure is scarcely explainable on the basis of its physiological and pharmacological action in large doses as thus far elucidated. In animal experimentation large doses have been found to exert a directly opposite action. Nor does this therapeutic effect seem explainable on the ground of promoting the elimination of calcareous deposits in the sclerosed arteries, since the removal of such deposits would probably take place much too slowly to account for the prompt reduction of blood pressure that frequently occurs. Besides, a more permanent reduction of blood pressure should be expected from decalcification of the arteries than occurs clinically.

The alkaline sulphocyanates are stable, distinctive, and biologically active substances, entirely different in their pharmacological properties from the deadly prussic acid and cyanide group. In sufficient amounts they exert potent and distinctive pharmacological properties, acting especially as intense spinal irritants, with lethal termination. For therapeutic use sodium sulphocyanate in doses of up to one gram daily (five grains three times a day) has been found markedly effective in reducing arterial hypertension.

Puerperal Sepsis in Wales

SIR EWEN MACLEAN, M.D., F.R.C.P.
Cardiff, Wales

The tables and diagrams exhibited, taken in conjunction with those for previous years, show that Wales has a consistently high maternal mortality rate and that the Welsh figures are much higher than the combined figures for England and Wales.

Further, the fact emerges that while the sepsis death rates are somewhat higher in Wales than in England and Wales, the chief disproportion is from other causes.

I have to thank the Registrar-General for permission to quote the figures in the accompanying table relating to 1923, which have not yet been published.

The three types of population compared are 1, county borough populations, which are truly urban in character; 2, other urban districts, which contain a large number of people living under semirural conditions; and 3, rural districts, the bulk of whose populations are country dwellers.

DISTRIBUTION FOR WALES AND FOR ENGLAND AND WALES OF MORTALITY OF WOMEN IN CHILDBIRTH, PER THOUSAND CHILDREN BORN ALIVE, DISTINGUISHING SEPTIC AND OTHER CAUSES, 1921, 1922, AND 1923

	1921		1922		1923	
	Wales	*England and Wales*	*Wales*	*England and Wales*	*Wales*	*England and Wales*
County boroughs—						
Sepsis 1.35	1.54		3.32	1.62	1.94	1.41
Other causes..2.99	2.40		3.34	2.28	2.67	2.60
All causes....4.34	3.94		6.56	3.90	4.61	4.01
Other urban districts—						
Sepsis 1.72	1.27		1.31	1.27	1.49	1.25
Other causes..3.47	2.76		3.77	2.68	3.92	2.57

All causes....5.35	3.91		5.43	3.81	5.42	3.81

It will be seen that in England and Wales as a whole, the death rate from sepsis is lowest in rural districts and becomes higher proportionately as the urbanization of the population increases.

With regard to the death rates from other causes the position is reversed. The more highly urbanized populations show the lowest maternal mortality from other causes. This may be attributable to the better medical and surgical facilities available and to the provision of maternity beds.

In Wales the sepsis death rates show no regular variation with the type of population concerned, but regarding deaths from other causes the table shows how much greater is the risk for the rural mothers than for the mothers in the urbanized communities.

Before proceeding to deal with some of the possible underlying causes of the outstanding position of Wales in the matter now under discussion a few general observations relating to the problem may be opportune.

The first report of the Welsh Consultative Council draws attention to the fact that the principality of Wales is a rugged and mountainous area, consisting for the most part of rural counties sparsely populated, with exceptional difficulties in intercommunication, but also containing some very congested industrial districts where the population has accumulated within recent years with a rapidity that has created unfortunate conditions for the amenities of life and the health of the people.

A special feature of importance is the marked contrast in population distribution existing between, on the one hand, the area covered by the geographical counties of Glamorgan and Monmouth, and, on the other hand, the area covered by the remaining eleven counties. The estimated population of Wales in the recent census (1923) is 2,704,000 in round figures. Of this total 1,765,000 reside in the geographical counties of Glamorgan (1,298,500) and Monmouth (466,500). Thus approximately two thirds of the entire population of Wales lives in two geographical counties, the remaining one third being spread over eleven counties, the average population of which is only 85,000 (round figures).

To return to the particular problem, we have sent in from the Maternity Department of Cardiff Royal Infirmary our quota of records of puerperal sepsis and these have been merged in the consolidated report of the obstetrical and gynecological section.

Apart, however, from the purely clinical and laboratory aspect of the subject, I venture to offer to the congress some observations arising out of certain visits of inquiry which, either personally or together with some colleagues of the Welsh Consultative Council, I was enabled to make to some seven or eight different centres in the principality during 1923-24.

On four of these occasions, one in North Wales and three in South Wales, being accompanied by some colleagues of the council and of the Welsh Board of Health, it was an especial advantage to meet at these centres the medical officers of health (county and district), and representatives of health committees, nursing associations, practising midwives, insurance committees, voluntary organizations, and others interested in general health questions. This conference was held in morning session, and in the afternoon the doctors of the area attended in goodly numbers, when a frank and unfettered discussion ensued. Nothing was more striking than the keen desire on the part of the members of the profession and of the various bodies represented and concerned to bring about a much needed and available betterment in the mortality and morbidity rates associated with childbirth and childbed.

I shall endeavor to indicate what appear to me to be some of the more important facts emerging and impressions gained at these local inquiries.

1. *Locality.*—As between rural, industrial and mixed areas it would seem that the incidence of maternal mortality from puerperal sepsis is not demonstrably influenced to an appreciable degree by questions of geographical location or by questions affecting population distribution.

2. *Midwives.*—Although the opinion was expressed by some medical practitioners that the old bona fide midwife was more likely to send for medi-

cal help on the occurrence of difficulties, the opinion of the doctors generally as well as of the various representatives was strongly in favor of a larger supply and a more satisfactory distribution of fully qualified midwives.

It was agreed that such a distribution might be effected on lines which allowed of a reasonable degree of freedom of choice by the patients and satisfactory sharing of the work by the midwives. A systematic distribution should also provide, by substitution or otherwise, for the contingency of midwives becoming "contact" with septic or other infective conditions.

3. It was generally agreed that subject to satisfactory distribution the midwives should be restricted to the practice of midwifery, but that where this was not practicable, for instance, in some rural areas, it was preferable to combine the duties of the midwife with those of the health visitor rather than with those of the district nurse.

4. Some divergence of opinion was evident as to the feasibility of establishing the status of what are called home helps in any health scheme. The really efficient home help must surely represent a consolidation of good qualities but rarely seen.

5. The value of maternity homes, maternity wards, and antenatal clinics was fully recognized at the conferences in all the centres visited. In certain areas local opinion had to be educated as to the essential value of these establishments in order to lead to their being freely used.

Prejudice in regard to the work of the trained midwives and health visitors had at first existed in considerable degree but had in large measure disappeared, and the evidence went to show that where lying in beds and antenatal clinics had been made available a similar experience had accrued.

To have the antenatal clinic within the curtilage of the maternity hospital had been found to be a convenient and educative arrangement.

In the larger towns it had been found of great advantage to link up the maternity ward or wards with the general hospital so that the service of the medical, surgical and special departments would, if required, be available for the expectant or parturient mother.

The importance of the medical officers of the antenatal clinics keeping in touch with the general practitioners and advising them of any abnormality discovered, was strongly emphasized, and in midwives' as well as doctors' cases the value of periodical examination of the urine during pregnancy was readily conceded.

6. In the rural areas especially care of the teeth during pregnancy was little thought of, and the adage "for every child a tooth" had been expanded into the prevalent belief that in the expectant mother dental caries was inevitable and its treatment undesirable.

At one of the inquiries a medical officer of health stated that the condition of the mouths of the mothers who attended the infant welfare centres was appalling, and at another conference a medical practitioner said that the condition of the teeth of the people generally was very bad, "that no woman ever thought of going to a dentist unless she had toothache, and that there was a fallacious general belief that women ought never to have their teeth attended to by a dentist during pregnancy."

In the rural areas there is, of course, difficulty in obtaining the services of qualified dentists.

7. *Nourishment of expectant mothers.*—In the more rural areas the inquiries went to show that the general standard of living of the mothers was poor, and their dietaries inadequate and poorly balanced.

In the smaller homes it was stated that the families seldom saw a fresh joint of meat; that milk was often unobtainable; that the people had not acquired a taste for fresh vegetables which could so easily be grown; and that they seldom had any form of fresh food. The family fare consisted too largely of tea and bread and butter. "The teapot never gets cold till late at night," and the tendency, even where produce was grown, was to sell the best of everything and keep the poorest for consumption at home. Statements were made to the effect that, even in these circumstances, the mothers by their own act "came last" and were often markedly anemic and debilitated, with the result that at the time of confinement their powers of resistance whether in regard to infection or other parturient risks were at the lowest ebb.

In the industrial areas, similarly, the unselfishness of the mother was an important factor, especially under the present economic conditions, both as regards improper and insufficient dietary and also as regards the strain of the almost continuous household duties in the colliery districts, for instance, where the husband, sons and lodgers may be engaged in different work shifts at the pits.

8. *Housing conditions and environment.*—Much evidence was forthcoming to show the need for the rousing of a more enlightened public opinion as to the capital importance of sanitation and other hygienic conditions.

Apart from the admitted shortage of housing accommodation, the dilapidation of existing houses and the existence of overcrowding which are unquestionably contributory factors in the problem, there remains the fact that even in present conditions there is scope for much improvement in the habits and customs prevailing in many parts of the country—improvement that can only be achieved by a vigorous educational effort by health authorities and all who are interested in bringing about a fuller appreciation of the laws of health—both by those who build the houses and by those who live in them.

In the country, the houses are often very small and badly ventilated. Many of the cottages consist of two rooms with a loft, and the flooring may be of mud or sometimes slate. As many as twenty per cent. of the houses have no sanitary arrangements whatsoever. There is too often a lack of personal and household cleanliness and a general disinclination to change personal or bed clothing. Occasionally women may be confined on the floor, lying on clothing already soiled, to save the bed.

In the industrial areas there is a great deal of overcrowding. In the Rhondda district over ten thousand families live in houses occupied by more than one family, and in this and other areas instances were quoted where two or more families lived in the same house, and that of small dimensions, with the result that confinements had often to

take place under the most undesirable and unseemly conditions.

The plea for the establishment of maternity homes and hospitals in such areas is overwhelming and is but slowly being responded to.

9. *Nondisclosure of puerperal sepsis.*—There is no doubt that, either avoidably or unavoidably, the requirements with regard to notification are not properly observed. For the five years 1918-1922 inclusive, while there were 503 deaths from puerperal sepsis in Wales and Monmouthshire, the number of notifications was only 579, and in some areas the number of deaths exceeded the notifications.

This important matter was fully discussed at all the meetings with the doctors, and there was general agreement that notwithstanding the disabilities in the practices of doctors and midwives which might accrue from notification of sepsis, the urgency of taking all steps to prevent the spread of the infection, as well as to secure such help in the management of the case as the local authority could furnish, should prevent in every case the avoidance of this responsible duty.

At the same time many of the practitioners drew attention to some real difficulties. And, firstly, as to the question of diagnosis, it was fairly stated that apart from pyrexial conditions which are quite independent of the puerperium, as such, and excluding also the socalled reactionary rises in the first twenty-four hours, temporary elevations of temperature from 100° to 102° F. may occur during the first week from errors of diet, constipation, emotion or other nervous disturbance, or from unimportant mammary conditions.

More guidance was asked for in regard to differential diagnosis. As desiderata it would appear to be considered that either a readily applied clinical test should be evolved or a more comprehensive formula employed as the basis for notification. The difficulties might be that with the former not a few cases of sepsis would escape detection, and that the latter would include more than all the cases of infection. At one of the meetings a recommendation was put forward indicating the desirability of district medical officers arranging with registrars of births and deaths of the subdistricts for the supply of earlier information of deaths caused by puerperal fever, as this would enable the medical officers of health concerned to make prompt enquiries as to actual and contributory causes.

Another handicap to notification was the objection thereto sometimes raised by the lying in woman herself or by her relatives and friends. Notification which results in nothing beyond visitation by various officials cannot be other than unpopular, but if and when it is followed by helpful service and, where necessary, institutional treatment, the prospects of its acceptance and efficiency are more assured.

Complacency is another contributory cause to inefficiency. This was especially illustrated by the discovery in one of the rural counties of the tradition that a mother recently confined *must* have a temperature, the condition being dignified by the title *Bradgyfarfod,* which, freely translated, may be taken to mean "a combative meeting," the factors in the combat being regarded as the lochia and the mammary secretion.

It is not contended that such a belief is generally current, but it would certainly be true to say that the existence and even the persistence of a temperature in childbed is far too often regarded by the patient and her friends with the minimum of concern.

10. *Attendance by doctors and midwives.*—There is considerable diversity in various parts of Wales in regard to the number of confinements attended by midwives only, and the number attended by doctors (with or without midwives). Thus, in Merionethshire, a rural county, the proportion of cases attended by doctors is very high, the figures being eighteen per cent. attended by midwives only, and eighty-two per cent. by doctors (with or without midwives). At the other extreme, in the Rhondda District (Glamorgan), eighty-four per cent. were attended by midwives only and sixteen per cent. by doctors (with or without midwives). Speaking generally these variable proportions, as between rural and industrial areas, prevail throughout Wales and Monmouthshire.

It would be fallacious to infer from these proportions that the rates of morbidity and mortality follow in either one direction or the other. Fears were expressed in some of the industrial areas that the high proportion of cases attended by midwives was disadvantageous to the patients, but on the whole it was found that in these areas the midwives are well trained and sufficiently impressed with the importance of sending for medical aid as occasion may require.

In the rural areas the dearth of trained midwives accounts for the large proportion of cases in which the doctor is engaged, and it is asserted, too, that the unskilled services of the handy woman contributed largely to the high sepsis rate.

It was agreed that an increased supply of qualified midwives is especially urgent for the rural areas.

11. *Ages of marriage.*—For the Counties of Wales and Monmouthshire a table giving the percentage of the total marriages of women contracted, 1, before the age of twenty-one, and 2, after the age of thirty-five, shows that in a given year (1921) there was a higher percentage of the early marriages in Wales (18.2) than in England and Wales (14.9), and a lower percentage in the later marriages (Wales 9.3, England and Wales 10.7).

It is of some significance that some of the counties showing the highest percentages of late marriages are also among those with the highest maternal mortality rates.

12. *Abortion.*—The impression was gained that abortion and attempted abortion, both by means of drugs and various instruments, is prevalent to a considerable and an increasing degree in the industrial parts of Wales. In one such area with Pontypridd as its population centre the figures show that 11.5 per cent. of the deaths arising out of pregnancy and childbirth were attributed to this cause.

13. *Use of forceps.*—The question of the use and abuse of the forceps was fully and frankly discussed at the doctors' meetings. There was common agreement in the view that while in a proportion of cases the use of the forceps was advisable or imperative, in no case could the mere saving of time of those in attendance be regarded as a justifiable indication, having regard to the admitted increase in the risks

of infection and injury which their employment entails.

As to the use of forceps generally, not a few of the doctors stated that they applied them much less often than was their habit some years ago, and that this was, in part at least, attributable to the good results of antenatal clinics as well as to pronouncements of some latterday obstetricians!

14. *Rubber gloves and sterilized obstetrical outfits.*—The doctors and the representatives of the midwives concurred in the view that the intelligent use of rubber gloves and the provision of sterilized outfits would do much to combat those domestic conditions which so largely increase the risks of septic infection.

15. *Notification of pregnancy.*—Compulsory notification, however valuable it might be as leading to adequate supervision during pregnancy, was regarded by all parties represented at the various conferences as an impracticable proposition.

It was thought, however, that the principle of voluntary notification would ultimately prevail when, by wise propaganda and the continued advice of doctors, midwives, and health visitors, the benefits deriving from voluntary notification were more generally appreciated.

SUMMARY AND CONCLUSION

The facts and responsible opinions emerging from these representative conferences justify the conclusion that the efforts which the community must make toward the solving of this urgent problem must include the following:

1. A more complete and better organized provision of thoroughly well trained and suitably educated midwives and health visitors.

2. A considerable extension of well supervised schemes for the antenatal supervision of mothers, both domiciliary and at clinics.

3. An extended and improved supply of milk and other necessary forms of nourishment for expectant and nursing mothers.

4. A substantial addition to the existing provision of maternity homes and of maternity wards in or in connection with the general hospitals.

5. Finally, I am convinced that by better organized clinical and laboratory research such further light can be thrown upon the predisposing and the actual causes of puerperal sepsis as will lead to a larger measure of prevention and to more effective treatment, and there can be little doubt that a real contribution to that end will be reckoned among the many good results of this congress.

Observations on Puerperal Sepsis*

EDWARD A. SCHUMANN, M.D., F.A.C.S.
Philadelphia, Pa.

Infection developing during the puerperal period and originating in some focus in the birth canal has ever been a source of disquietude to obstetricians and a potent factor in the mortality and morbidity which all too often follow childbirth.

For a clear understanding of the subject, it would seem that the term puerperal sepsis, while undoubtedly proper in a generic sense, requires further subdivision and classification for more accurate diagnostic localization, as well as for treatment.

The genital tract from the tubes and ovary to the vulva may be the primary seat of infection during the puerperium although its component tissues vary greatly in their susceptibility to invasion by pyogenic bacteria. The vulva and vagina are strongly resistant, although Bartholin's glands may become converted into abscess sacs, while the bacillus of diphtheria and the pneumococcus sometimes are the causes of grave vaginitis. The cervical mucosa is a fairly common seat of infection, but the usual site of the original inoculation is the degenerating decidua, especially at the placental site.

The etiology of puerperal sepsis is very simply explained. An overwhelming majority of cases are due to the spreading of a local wound infection, pyogenic bacteria being brought into contact with the laceration attendant upon delivery, even though these lacerations be minute and confined to the decidual surface of the uterus.

In a comparatively small number of instances, the infection is autogenous, due either to the recrudescence of a latent adnexal inflammation, or to the development of bacteria in the birth canal from a remote focus of infection, appendix, gallbladder, kidney, pelvis, tonsil, or even abscessed teeth.

A survey of carefully kept records over a number of years discloses some interesting facts. Lea has said that "the general introduction of anesthesia into obstetrical practice is responsible for a marked increase in puerperal sepsis. Prior to this event, operations were undertaken rarely and with reluctance, but with the general use of ether and chloroform they were performed with increasing frequency and a distinct increase in mortality can be traced to this fact. Thus, while in 1847 to 1856 the mortality did not exceed 1.8 per thousand in England and Wales, in spite of the absence of antiseptics in the years 1875 to 1884 this has increased to 2.4 per thousand (almost double) and has as yet shown few signs of diminution.

It must be recognized, however, that while sepsis increased in proportion to operative deliveries, so did the mortality from accidents of childbirth decrease, and by comparison with the same periods, an accidental death rate of 3.56 per thousand in the decade between 1847-56 was reduced to 2.28 in the period from 1875-84. Thus, although the risk of sepsis was greater the maternal death rate from all causes was lessened from 5.27 to 4.57 per thousand in the same period.

It follows then, that with greater knowledge and

*Read before the Buffalo Academy of Medicine, April 15, 1925.

power among obstetricians for successful operative deliveries there has resulted an increase in the puerperal sepsis rate, but a net improvement in obstetrical results despite this increase.

That the reduction in maternal mortality is so slight, in spite of the enormous development in operative technic and in the individual employment of aseptic methods, is a severe indictment of the profession, since puerperal sepsis is a preventable disease and the great majority of its victims die as the direct result of improper attention to the details of asepsis on the part of the medical attendant, the nurse, or both.

After delivery there are always present many smaller or larger lacerated wounds in the birth canal, particularly on the uterine surface where the placenta has been attached or when small portions of endometrium have been scraped away during the passage of the fetus. These local wounds are the seat of the primary infection in most cases.

TYPES OF PUERPERAL SEPSIS

If we admit then that puerperal sepsis begins as a localized endometritis it may develop in various ways and run widely different courses.

1. The infection may remain localized in the endometrium, with necrosis and sloughing of the membrane and with no general symptoms save a mild elevation of temperature.

2. The infection may remain localized, as indicated above, but from the multiplication of saprophytic or putrefactive bacteria there may be a systemic absorption of bacterial endotoxin with markedly septic temperature curves, and some elevation of the pulse rate, the condition being known as puerperal sapremia.

3. The infection may remain localized but the invading organisms being of a high degree of virulence, may penetrate the reaction zone in the uterine wall, enter the blood stream and eventuate in septicemia—the socalled blood stream infection of deadly activity, possibly terminating in pyemia with multiple abscess.

4. The infection may spread by continuity, and involve the veins of the broad ligaments causing septic thrombophlebitis of these vessels.

5. Small necrotic masses, bacteria laden, may enter the tubes and cause salpingitis.

6. General peritonitis may occur either as a result of leakage from the fimbriated extremity of an infected tube or by transmission via the blood or lymph streams.

The mechanism of these several terminations is best explained by reference to the balance between individual resistance to bacterial invasion, and to the specific activity of the bacteria involved. Thus, should the infection be due to the ingress of purely saprophytic germs a sapremia of low degree will result in a woman of good resistance. However, if the resistance be poor, even saprophytic bacteria may develop an increased toxicity and give rise to the more severe forms of inflammation.

When organisms of high virulence are the source of the infection, widespread lesions follow rapidly, the Streptococcus hemolyticus pyogenes being possibly the worst offender.

The diagnosis of these several types of puerperal sepsis is most important since any hope of success in management lies in a correct interpretation of the nature of the disease processes to be combatted.

SYMPTOMS

The early symptoms are almost universally restricted to a moderate rise of temperature accompanied by a slight chill, on about the third day after delivery. At this time the infection is localized in the endometrium, the first febrile reaction being usually due to a toxic absorption—the sapremia of the older writers. There may be present some abnormal odor to the lochia. Within forty-eight hours the progress of the condition will become manifest. If the invading organisms are of low vitality and the natural resistance of the patient high, the disease will remain local, the wall of exudate, phagocytes and small round cells will not be penetrated and a rapid return to normal takes place. The temperature falls, the rigors cease, and the lochia loses its foul or sweetish odor. This happy termination, however, is not the rule. More frequently the inflammation becomes widespread taking one or more of the forms described. The onset of pain usually predicates salpingitis, pelvic cellulitis, thrombophlebitis of the broad ligament or a beginning general peritonitis.

If pain be generalized in the pelvis, and vaginal examination discloses an induration about the lower uterine segment with fixation of the cervix and extreme tenderness on palpation of that organ, pelvic cellulitis is to be strongly suspected. When pain of marked severity develops in one or both iliac fossa, with rigidity of the recti muscles, occasional vomiting, a sharp rise in the leucocyte count and the presence, on vaginal examination, of more or less indefinite masses in the tubal region, acute salpingitis with some degree of pelvic peritonitis is the probable lesion.

When pelvic pain is steady and severe and extends down the thigh, the temperature running a septic course but not excessively high, with very marked tenderness in the vaginal vaults but no definite masses, thrombophlebitis of the veins of the broad ligament is the probable causal factor.

General peritonitis discloses its presence by its usual dread manifestations; vomiting becoming dark brown, a dry, brown tongue, meteorism, cessation of peristalsis, generalized abdominal pain and a rapid running pulse.

Lastly, septicemia, the so common termination when the bacteria are of high virulence, is possible of diagnosis even before the detection of a positive blood culture by the entire absence of subjective symptoms in a woman who is obviously desperately ill.

Questioned as to her symptoms such a patient will express a sense of well being, will inquire as to how much longer she must remain in bed and on examination will present very few signs of illness. The abdomen is flat and soft and not tender, the lochia is normal and only the very great temperature excursion, 105° to 97° in twelve hours, the rapid pulse and the progressive anemia and hemolysis give evidence of the gravity of the situation.

Attention is called to the fact that while didactically expressed, the varieties of puerperal sepsis form a series of sharply differentiated clinical pictures, this is by no means the fact in actual practice. One set of lesions is so frequently superimposed on another that diagnostic features become obscure and great difficulty arises in reaching a conclusion.

There is one practical point in this connection which I beg to emphasize, and that is, the necessity for frequent physical examination of these patients.

All too often a case is diagnosed as "puerperal sepsis" and treated along general lines, the forming pelvic abscess being entirely overlooked or the blood stream infection allowed to progress without knowledge of its existence. Like all diseases involving purulent processes, the characteristic features change with sometimes startling rapidity, and constant and close supervision is obligatory in order that the medical attendant may snatch the moment of election for the evacuation of some localizing collection of pus.

In order not to extend this paper unduly, infections of the vulva or vagina have not been included although they form an integral portion of any complete consideration of infections developing after labor.

Sepsis of autogenous origin must, however, be given some place in such discussions. A preexisting, salpingitis will occasionally be lighted into activity by the traumatism and congestion incident to labor with the development of signs of peritonitis within a few hours after delivery. The diagnosis will usually be made clear by the rapidity of onset; much too soon for infection spreading from a local source in the endometrium.

Occasionally, a remote colony of bacteria will be excited to renewed activity during labor and being transmitted to the uterine area of least resistance by way of the blood stream will then produce the usual lesions of acute infection. The appendix, gallbladder, kidney, pelvis and even the teeth and tonsils may furnish such autogenous foci.

The diagnosis of this mode of origin is difficult and rarely certain, but a history of the existence of an old site of inflammation together with the early onset of symptoms may give rise to the suspicion that such is the underlying pathogenesis.

PROGNOSIS

The mortality of puerperal sepsis may be said to increase in direct ratio to the virulence of the bacteria and their ability to penetrate the granulation zone set up in the defense of the tissues and inversely with the resistance of the patient and the power of her phagocytes to destroy the invading organisms as they enter the blood stream.

The general mortality is about thirty per cent., but this figure should be separated since the prognosis is so different in different types of infection. Thus, septicemia especially when the causal organisms is the Streptococcus hemolyticus pyogenes will show a death rate of from sixty to eighty per cent., while sapremia will be fatal in but one or two per cent.

Localized infection, cellulitis, salpingitis, carry a low mortality, while that attendant upon general peritonitis is frightful, at least eighty-five to ninety per cent. Whatever the type of infection, the prognosis should always be grave and the case regarded as one of the utmost seriousness.

MANAGEMENT

The treatment of puerperal sepsis divides itself easily into prophylaxis and cure. The former offers a beguiling subject for debate since it leads to a consideration of broad obstetrical policy and indeed to a review of the whole matter of methods of delivery.

It was stated at the beginning of this article that infection of the parturient woman increased in almost direct ratio to the general use of operative and manual methods of delivery, which were facilitated by the introduction of anesthesia. From this fact one would deduce that invasion of the birth canal, either manually or instrumentally, should be reduced to the minimum limit to prevent contamination. When one considers the matter, however, it becomes apparent that such deduction would be manifestly false, since we have many examples of the boldest intrauterine manipulations without untoward results. In this city there lives an obstetrician who has engaged in more manual explorations of the parturient uterus than any other man of any time, and while I do not have Potter's statistics at hand, I venture the assertion that the occurrence of puerperal sepsis in his practice is so small as to be negligible. In Chicago, the general use of prophylactic forceps plus a major vaginal operation, by De Lee, has certainly shown a low incidence of infection. With these two examples, it is clear that the uterus may be invaded with safety and that the cause of sepsis does not lie in this procedure *per se*.

The whole question resolves itself into one of surgical asepsis. Given an obstetrician with the aseptic conscience, properly trained in surgical technic, and he may enter the uterine cavity with perfect impunity, when and where he will.

The problem is the old one of better obstetrical training and the making of so profound an impression upon the mind of the student as to the absolute and unceasing necessity for the maintenance of aseptic technic in the practice of obstetrics, that he cannot lapse in after years, even though he would.

MANAGEMENT

The management of puerperal sepsis, when it has been established, may be considered under the heads of local treatment, general systemic measures, and the methods of sterilization of the blood stream, to which may be added operative procedures. Inasmuch as most cases begin as an endometritis of some kind, local treatment was long held in high esteem and many instruments have been designed to facilitate the removal of necrotic material from the uterine cavity. Happily this erroneous treatment has generally been abandoned since it has been shown that attempts to remove the infected endometrium are usually fraught with disaster.

The only barrier between the bacteria laden decidua and the blood stream lies in the zone of granulation tissue which rapidly forms and which may maintain localization of the disease process.

Instrumental emptying of the uterus, no matter how delicately performed or how blunt an instrument is used, is certain to break down little areas of this granulated tissue, thus opening the great uterine blood spaces and the retroplacental thrombi to bacterial attack.

Furthermore, since the infection has become general, at least in a measure, within a few hours after the implantation of the causative organisms, it is of no therapeutic value to remove the original site. De Lee has well said that it is as logical to curette the fauces in diphtheria as the uterine cavity in sepsis.

It is my belief that the curette, the placental for-

ceps, and even the gloved finger have no place in the treatment of septic endometritis in the puerperium. How then shall we reduce the infectivity of the germ laden tissue and what measures may we take to hasten its expulsion?

Both of these indications are best met by the maintenance of uterine contraction and the establishment of free drainage. The former desideratum may be obtained by the frequent exhibition of pituitrin and the various ergot preparations. At the Jefferson Hospital we are in the habit of giving five drops of pituitrin at intervals of three hours and a combination of fluid extract of ergot, fifteen drops, with strychnine sulphate one thirtieth grain, three times a day. An icebag over the lower abdomen relieves congestion and facilitates contraction.

Drainage is best established by postural methods. Raising the head of the bed about sixteen inches and encouraging the patient to change her position frequently, lying now on one side and now on the other and occasionally turning on her abdomen for a short time, will best serve this purpose. Some obstetricians prefer the Fowler bed, but in my experience the discomfort suffered by the patient and her comparative bodily immobility far outweigh any advantage gained.

Septic material accumulating in the vagina must be removed by gentle irrigation at frequent intervals—at least twice, usually four times daily.

In certain cases where the infection remains apparently localized in the uterine cavity, but shows no tendency to resolution, attempted sterilization by Dakin's fluid, is occasionally attended by surprisingly good results. This method was strongly advocated some years ago by Sherman, of Pittsburgh, who introduced a small rubber tube perforated with minute openings (the regular Carrel-Dakin tube) into the uterine cavity, placed a light dam of gauze about the cervix and then instilled Dakin's solution by the continuous drip method. The gauze is to be changed daily, and should never be placed too firmly to allow free return of the fluid by seepage through it, without distention of the uterus. This plan of treatment is worthy of more general use than it has enjoyed.

No further local measures are advised. The general treatment consists wholly of procedures tending to increase resistance, combat dehydration and prevent anemia. Frequent transfusions, using small amounts of blood, are by all odds the most important feature of the treatment. Two hundred to three hundred c. c. of properly typed blood transfused by the Unger direct method and repeated at three to four day intervals have shown excellent results. By this means the rapidly progressive anemia is withstood and the general strength of the patient maintained. Abundant food, such as milk, broth, meat juice, and other nourishing liquids, is a necessity and moderate doses of alcohol in the form of milk punches are most valuable.

Dehydration is met by the use of proctoclysis, sodium bicarbonate solution in five per cent. strength being the fluid employed. Restlessness should be controlled by the administration of morphine and chloral and if at all possible the patient should spend her days in the sunshine and the open air if this can be arranged.

Sterilization of the blood stream in the presence of bacteriemia has been the goal of surgeons for years, many antiseptics having been employed with but indifferent success. The work of Piper of Philadelphia, using mercurochrome, has revived the hopes of those who have followed his results and seems to offer more hope of ultimate success than any plan yet devised.

Piper's technic is fully described in his original communication on this subject (1) and is therefore briefly epitomized here.

Immediately upon the discovery of a positive blood culture, the patient is given an initial injection of two thirds maximum dose of a one per cent. mercurochome solution in sterile water, the dose, based upon Piper's research, being thirty c. c. for the first one hundred pounds of body weight and five c. c. for each additional thirty pounds. Beyond thirty c. c. the dose is increased very gradually, especially if there is any question as to renal efficiency. The solution is injected intravenously with a salvarsan syringe and as slowly as may be. Within from thirty minutes to six hours there will occur violent diarrhea, red stained urine, probably very much reduced in amount, some vomiting and nausea.

There is usually a distinct chill lasting as long as a half hour and a rise of temperature to 105° or even higher. These evidences of reaction usually subside within forty-eight hours, after which another injection of thirty to thirty-five c. c. is made. Shock during the reaction is met by the administration of adrenalin, strychnine, or other cardiac stimulants, diarrhea is combatted by the administration of opium, belladonna and bismuth, and the chill is treated by local external heat.

Since blood stream infections always predicate a desperate state of affairs, the clinical results of this treatment, while still far from satisfactory, are by contrast with any other method so excellent that some hope is offered for at least partial success in the management of this, the most distressing and fatal of all obstetric complications.

Surgical intervention is indicated, to my mind, only when definite evidence of localization of pus is present. The pelvic abscess is to be drained, the purulent tube and the cornual abscess in the uterine wall excised, but beyond this we have not seen any gain by surgical methods of contrast.

Considerable controversy arose some time ago regarding the excision of the thrombotic veins of the broad ligament, but the operation has fallen into disuse, its results being in the main unsatisfactory.

Early hysterectomy has had its advocates and seems a logical plan of treatment, but since septic patients are poor surgical risks, and as the infection has probably already progressed beyond the limits of the uterine wall, the procedure has not met with general adoption.

The management of general peritonitis following puerperal infection is that of peritonitis in general. Whether one is an apostle of conservatism, or of radical operative intervention, the end results are approximately the same, a frightful mortality, with only an occasional recovery to brighten the darkness of the picture.

Much more time might be spent in a consideration of the protean phases of this most important and interesting aspect of our work, but in a brief article

of this character one may only skim the surface, giving a very brief outline of a few of its more important and outstanding phases.

CONCLUSIONS

In conclusion, I beg to submit four theses:

1. An accurate diagnosis of the particular lesions developing in a case of puerperal sepsis is necessary to its intelligent management.

2. Intrauterine manipulation is not *per se* a cause of infection, but failure to apply the principles of surgical asepsis to obstetrical medicine is the usual cause of the disease.

3. Local intrauterine treatment is productive of great harm and little good.

4. Chemical sterilization of the blood stream offers the only hope of successfully meeting the most fatal of septic terminations.

The Education of the Asthmatic*

GEORGE N. JACK, M. D.
Buffalo, N. Y.

The asthmatic must be taught how to protect himself as much as possible from the agents which precipitate an attack, such as horses, cats, frosty air, hematolytic and night atmospheric gases, and other causes. Some cases of complicated asthma and the uncomplicated cases which are extremely sensitized to periods of blood disintegrating, meteorotelluric phenomena, as the fall and spring equinoctial seasons, should, during these seasons, either migrate or stay in the house, and sleep in a bedroom as high in the air as possible, protected with a gas filtering ventilator and kept at a blood stabilizing temperature, light and humidity. At this time they should also eat as little food as possible (1).

The asthmatic must know the nature of his trouble. He must know why he should take treatment. He must know that in some uncomplicated cases of asthma the patients, without treatment, would have become suffering invalids, while through a knowledge of the nature of their trouble and the object of their treatment they have had sufficient faith and confidence in the treatment to continue it, in spite of many discouraging attacks, thus enabling them to lead useful and selfsustaining lives.

The treatment of asthma is largely educational. The asthmatic must be taught that there is no specific cause or treatment for asthma, but that treatment must be prescribed and varied as indicated by physical examinations and a study of the blood, urine, sputum and stools.

The asthmatic must be taught to diminish or stop his prescribed blood deficient biochemical medicines when his unstable blood is in food, metabolic, meteorotelluric, physicochemical equilibrium, in order to encourage his blood to draw its deficient chemicals from the prescribed, indicated diet and the prescribed hygienic or sunshine treatment.

The asthmatic should know that his unstable blood is hypersusceptible and sensitized to numerous disintegrating agents. The normal blood and tissues contain hydrogen, oxygen, sulphur, chlorine, iodine, fluorine, nitrogen, phosphorus, carbon, silicon, potassium, sodium, calcium, magnesium, arsenic and iron. The blood of the asthmatic is seasonably and periodically deficient in many of these elements, which should be prescribed in the form of medicines and a proper diet. When a deficient blood element has been determined, it should be administered separately and not in combination with other deficient elements so that it may be diminished or stopped as the blood draws it from the prescribed diet or from sunshine treatment.

The asthmatic should know that the unstable blood of most asthmatics is sensitized for life to certain meteorotelluric phenomena and certain gases. He should also understand that the unstable blood of most asthmatics imperfectly nourishes their capillaries, which gives them for life an accumulative diathesis which, if not counteracted by indicated starve periods, will automatically disintegrate the unstable blood of these patients, resulting in attacks of asthma.

Having furnished the asthmatic with a knowledge of his handicaps, we must then endeavor to educate him how to best live with them, just as we supply an artificial limb to a one legged man and teach him how to use it. The asthmatic should know that recent discoveries concerning asthma have, when intelligently applied in the treatment of asthma, robbed it of its indescribable suffering and disability.

The application of these principles has been so successful in preventing disability and prolonging life in uncomplicated cases of asthma that a life or sick benefit insurance company need not hesitate in accepting the uncomplicated case with the patient's signature to a proviso agreeing to present himself to his family physician once a month for examination and promising to cooperate as to indicated dietetic changes, seasonal prophylactic measures, medicinal aids, change of environment, occupation, and other factors.

In many cases of complicated asthma the patients may also be educated to live without incapacitating attacks and to work at their chosen occupation, as shown by the following case:

Case I.—No. 601. Mr. J. G. P., April 27, 1914, Buffalo, N. Y., aged fifty-five, referred to me by Dr. Irving W. Potter. When I was called, patient was ill with asthma and bronchopneumonia. In a short time patient became delirious and I called Dr. Potter back for a consultation, as I feared the patient would die. However, he gradually recovered and on May 27th had no asthma. On June 11th he came to

*Read before the American Association for the Study of Allergy at Atlantic City, May 26, 1925.

my office. Weight 123 pounds. Patient had had asthma in a severe form for the last ten years, sitting up nights with attacks, and a rectal fistula for eighteen years, which was still discharging pus. He is still under my care, and during these eleven years he has suffered with but little asthma and has worked every day except when occasionally off in the spring of the year with short grippelike attacks. He has worked as foreman of a planing mill at this time. His fistula would heal and then break open again; at present it is healed and he is doing fine. He feels that his asthmatic troubles are over.

The asthmatic that is educated to assist in avoiding asthma, protects himself when possible from blood disintegrating agents as night atmospheric gases and other hematolytic gases as swamp, subtropical, tropical, barn gases, sewer gases, and others, and cooperates in fortifying himself against blood disintegrations by utilizing blood stabilizing agents as outdoor sunshine and sun electromagnetism, altitude, oxygen, ozone, open air, a well balanced indicated diet, and indicated blood rechemistration.

The asthmatic, in order to cooperate intelligently in the prevention of asthma, must know something about its pathology. He must know that after his unstable blood disintegrates with its resultant attack of asthma, it dumps its disintegrated material along the line of least resistance which in the asthmatic is the mucous membranes of the respiratory tract.

The blood dumping process first starts in the head, giving the characteristic watery eye and sneeze or coryza, second in the laryngeal pouches, pushing the false vocal cords into the lumen of the larynx and giving them a valvular action, which obstructs the expired air current with the characteristic wheezing dyspnea or attack of asthma. This laryngeal dyspnea soon loads the blood up with carbon dioxide and dilates the capillaries of the mucous membranes of the trachea, bronchi, bronchioles and air cells, rendering the walls of the air cells and bronchioles congested, distended, erectile and noncollapsible which rapidly results in a respiratory block or severe attack of asthma.

If the blood disintegrating agent was a hypodermic injection of a raw proteid, it constitutes an anaphylactic shock and frequently death from asphyxia. There is no spasmodic contraction of the air tubes in asthma or in anaphylaxis.

The dyspnea of asthma or anaphylaxis is often relieved by any agent that contracts the capillaries as adrenalin, pituitrin, strychnine, morphine, atropine, quinine, ergot, and other drugs. A spinal cupping followed by a capsicum rub helps to relieve asthma by increasing the adrenalin output and stimulating the nerves.

Adrenalin is only a temporary relief for asthma. Many asthmatics come to me with their legs and arms so black and abscessed that there is no more space for another hypodermic needle and their asthma is no longer even temporarily relieved by these hypodermics, as shown by the following cases:

Case II.—No. 1308, July 12, 1923, Mrs. H. A., Grand Island, N. Y., aged thirty-two, weight 139 pounds, married eight years, two children, asthma since the age of seven, attacks came on and off until seven years ago; asthma severe with two pregnancies and extremely bad for last seven years. Asthma most of the time, sitting up night after night. Was in bed last year from August to October and not able to work until February. She had a slight rise in temperature with the asthma during this sickness. A great deal of coughing with soreness in the chest, especially in the region of the trachea. She had night sweats with the asthma. There was considerable intestinal gas and the asthma was worse after eating, especially supper. She had an operation on her nose three years ago. Five years ago she almost died from influenza—in bed five weeks. The bowels were constipated. Her father had had rheumatism all his life.

This patient had given herself hypodermics of adrenalin for five years and her arms and legs were black and blue and full of needle abscesses. The hypodermics at first gave her but short periods of relief and then failed to do even that. The patient is still under observation and while she has a few reminders of asthma in the fall of the year, has not had to sit up nights or lose any time from work. She had but one severe attack of asthma on September 5th while visiting in Toronto, where she called in a physician for a hypodermic of morphine and atropine.

Case III.—No. 1375, January 22, 1924, Miss M. M., Elmira, N. Y., aged twenty-three, weight 136 pounds, occupation teacher, asthma for two years. Often sat up all night with severe attacks and was up every night two or three times. Had had several operations on the nose since her asthma began and last June had her tonsils removed, after which she was extremely ill, had asthma night and day and sat in a chair for a week. For the last year and a half she had been giving herself hypodermics of adrenalin three or four times a day. Her arms and legs were black and blue and full of needle abscesses. The hypodermics finally gave her but a few minutes' relief. This patient responded satisfactorily to treatment but her cough persisted for some time with uncomfortable asthmatic reminders for which she would occasionally resort to adrenalin until February 5th, when she discontinued its use. She had lost the sense of smell from her nasal operations and her nasal polypus returned so she had to have it removed in November. At the last report, she still coughed at night but had no asthma. She was not able to teach for one and a half years, although continually under treatment. This year, 1925, she is doing private tutoring.

In uncomplicated cases the patients, if properly instructed and are cooperative, seldom require anything for temporary relief, such as adrenalin, morphine, cocaine or gin.

A study of 1,408 cases of asthma during the last thirty years has demonstrated that in the majority of uncomplicated cases the patients can be educated to live without incapacitating asthma. Many of these patients have had no signs of asthma for years, as shown by the following cases:

Case IV.—No. 88, August 28, 1905, Miss J. E., Buffalo, N. Y., aged thirteen, asthma since two years old, attacks coming every seven to thirty days and lasting from three to six days, sitting up nights during the attacks. The patient is still under observation, which gives a period of twenty years' study. May 8, 1908, the patient began to menstruate, at the age of sixteen. The patient had a few attacks of asthma when she would go to the country and stay over night in the fall of the year. She also had a few

attacks at home, during the spring and fall of the year. On June 18, 1923, the patient stated that she had had no asthma for eleven years, except two attacks, one at Port Maitland, June 16th. The patient was last seen October 9, 1924, when she was still free from asthma. She is now married and has two children.

Case V.—No. 150, February 10, 1909, Mrs. V. T. Greenwood, N. Y., wife of farmer, referred to me by the late Dr. Harvey P. Jack, of Hornell, N. Y. She had had asthma for seventeen years almost constantly day and night, always worse in April, September and October. She was better in the dry summer months of June and July. She gave a family history of rheumatism. This patient has practically had no asthma from the time she began treatment up to present time. On October 8, 1920, she had a little reminder and a weak spell, which seemed to be due to low blood pressure. October 24, 1921, she moved from a hill to a valley where she had considerable bronchitis and cough but no asthma.

Case VI.—No. 698, March 2, 1915, Miss T. Z., Buffalo, N. Y., aged nineteen, weight ninety-two pounds, referred by Dr. George L. Fischer, Buffalo, N. Y. Asthma since three months old, every night, more or less, and a bad attack about once a month which compelled her to sit up nights. Was worse in the summer-autumnal season. She had had convulsions until three years of age. Menstruation began at age sixteen and occurred but once every two months. This patient has worked every day since I saw her and has had practically no asthma. Patient still under observation.

In about eighty per cent. of my uncomplicated cases of asthma I have been able to educate my cooperative patients to live as these asthmatic patients have, without incapacitating attacks.

The following case shows that in some cases of complicated asthma where the unstable blood is extremely sensitized to seasonal blood disintegrating meteorotelluric phenomena, the patients should migrate or hibernate during their unfavorable seasons. This case also shows how the asthmatic can be educated to overcome his handicap.

Case VII.—No. 1111, September 11, 1920, Mr. W. K., Lancaster, N. Y., farmer, aged fifty-five. Patient had had asthma for twenty-five years. Sat up nights every fall. Asthma not so bad in the middle of winter and in the summer. In May, 1921, the patient had a dropsical condition of his face, feet and hands due to his impoverished blood. The blood dropsy disappeared by July 1st. This patient is still under observation and he has worked hard on my farm, spring and summer, with no signs of asthma. However, the cold dewy nights of November would bring on asthma and he would be laid up for about two months.

Last summer I got him to take clabbered milk, vegetable, fruit diet, and after testing him out I added a hard boiled egg to his breakfast and beef, lamb or fowl to his noon meal. He worked all summer and felt well, with no asthma of any account and no blood dropsy. On November 9th he had an attack of asthma and we thought that he was in for his usual hibernation. I got him interested in my gas filtering ventilator for his upstairs bedroom and had him keep a fire going all night.

To overcome his blood dropsical tendency, which was due to a blood extremely low in blood elements or chemicals, his diet was corrected, adding more vegetables. His blood rechemistration treatment was increased by adding, when indicated, other blood elements or chemicals as potassium nitrate, sodium phosphate, ammonium chloride and sulphur. He was taught to wrap a woolen scarf, that had been saturated with naphtha gas by keeping it, when not in use, packed in a paper sack containing naphtha balls, over his nose and mouth to warm and soften the inspired air, when walking out in the cold, dry, frosty air.

As a result of these suggestions and blood rechemistration additions, he went through the winter of 1924-25 without any serious trouble. He was in the barn every day and was not propped up one night with pillows, for the first winter in twenty-eight years.

The asthmatic's unstable blood, when in equilibrium and when fed within its metabolic limit, is not sensitized to foods, any more than that of normal people. From a study of 1,408 cases I have found only three patients who were positively sensitized to foods, when their blood was in equilibrium, one to buckwheat and two to fresh fish. Sweet milk has given several asthmatics an acidosis so that it had to be changed to clabbered milk. I have never produced an acidosis with clabbered milk.

There are many agents that will disintegrate the unstable blood of the asthmatic so that an attack of asthma results. The agents which disintegrate it most frequently are heat retention humidity, chilly humidity, hematolytic atmospheric gases and putrefactive products reaching the blood through food, water, or as a result of intestinal putrefaction, traumatic, puerperal, postoperative, venereal, inoculative or focal troubles and accumulated metabolic products.

The reverse or the accumulation of septic material resulting from a blood disintegration producing swollen, lymphatic glands, tonsillitis or boils is more frequently the case.

The following case shows what can be accomplished by educating an asthmatic with an extreme and unusual complication.

Case VIII.—No. 1269, October 18, 1922, Master E. M., Buffalo, N. Y., aged eleven, weight sixty-three pounds. Patient was a blue baby at birth and is still blue with congenital cyanosis, blueness more pronounced with attacks. He has asthma most of the time, but severe attacks four times a year, worse in the spring and fall. He had influenza in 1918, was in bed for seven weeks. This was followed by running ears, which he still has at times. Tonsils were removed at four, and he nearly died during the operation from the effects of ether. Patient was first seen in bed with one of his severe attacks which compelled him to sit up day and night. He is still under treatment and has had no severe attack except on September 9, 1923, when he was compelled to sit up for one night. Patient had whooping cough in the summer of 1924 but no asthma with it. On May 9, 1925, his weight was eighty-four pounds and he is going to school and playing games as he has not done for three years.

Duke (2) has demonstrated how the capillaries respond to cold and other physical agents. Dry, frosty

air congests the capillaries of the asthmatic's air tubes and produces dyspnea. This will be relieved on entering a warm room unless it is severe enough or long enough to produce a suboxygenation, blood disintegration, in which case it results in a genuine attack of asthma.

The blood is the biochemical medium between meteorotelluric phenomena on the skin respiratory side and the food on the gastrointestinal side, therefore everything pertaining to life has a good or bad influence on the asthmatic.

A study of 1,408 cases of asthma during the last thirty years has demonstrated that asthma is due to an unstable blood condition, that the attacks are caused by a disintegration of the unstable blood, and that the instability of the asthmatic's blood renders it hypersusceptible and sensitized for life, in many cases, to numerous hematolytic agents, the chief of which is hematolytic, meteorotelluric phenomena.

Many asthmatics have complications which need special treatment. Those having tuberculous complications or with marked tuberculous tendencies should have the attitude or mountain treatment where they will encounter less hematolytic heat humidity retention and less hematolytic, atmospheric gases.

Asthmatics with heart complications or with marked nerve exhaustion should have rest treatment. Asthmatics with marked gastrointestinal disturbances need special treatment. Many asthmatics have ruptures and hemorrhoids which must be attended to.

After the unstable blood of the asthmatic disintegrates and becomes loaded with disintegrated material sufficient to produce an attack of asthma, it flows in small, dark drops with a high viscosity, rapid coagulation, thick consistency and a rapid, dirty brown, hydrogen peroxide reaction. When viewed under a microscope the cells are characteristically glued together forming an opaque, shapeless, adherent mass, requiring an unusual degree of pressure on the cover glass to differentiate the cells. The cells, when differentiated, shows that many of the erythrocytes are disintegrated as shown by their granular, star shaped appearance. The leucocytes are often increased; neutrophiles are often found; eosinophile cells are generally increased. The blood is slow to be absorbed by the test paper and shows a high hemoglobin scale.

The urine is characteristically dark brown or bloody brown, with a high specific gravity, and showing an acidosis and indican. At this stage the blood's metabolic equilibrium is reversed and its existence depends upon its ability to dump disintegrated material instead of absorbing nourishment. The blood now is sensitized to all foods and all foods should be withheld. Food, if taken at this stage, simply putrefies, thus adding poisons to the already overtaxed, disintegrated blood. During the urgent struggle of the blood at this stage to maintain its vitality, the patient should be kept quiet, as the least exertion produces a fatigue intoxication.

Dry, hot air, or a room temperature of seventy degrees with sunlight in the day time or an electric light at night, will aid the blood in dumping its disintegrated material by increasing its vitality.

If the disintegration is followed by a marked febrile reaction the fever aids the blood in dumping its disintegrated material to such an extent that this disintegration is generally not followed by asthma. The asthmatic should, therefore, never take anything to reduce his temperature as aspirin, the salicylates, antipyrine or the coal tar products.

The temperature of the body should be increased by hot clay poultices, hot foot baths, the drinking of hot water and the inhaling of hot saltpetre smoke. The hot saltpetre smoke inhalation also favors blood dumping by expectoration. The blood dumping should also be assisted by castor oil catharsis. Ipecac emesis or vomiting also assists the blood dumping process.

After the process is completed, the blood reaches the anemoequilibrium stage. At this stage the blood flows in large, rapid forming drops with a low hemaglobin scale and rapid test paper absorption. The blood now has a low viscosity, slow coagulation, thin consistency and a pinkish white, hydrogen peroxide reaction. Under the microscope the blood spreads easily and has a marked rouleau formation, often appearing in island like groups.

The urine is usually quite abundant, of a low specific gravity, of a pale, whitish color, and slightly acid in reaction.

At this stage feeding should cautiously be started, beginning with a whey diet and orange juice and gradually increased to clabbered milk and well cooked vegetables. If the asthmatic, at this intermediate or anemoequilibrium stage, eats beyond his blood's metabolic capacity, the viscosity of the blood becomes high, resulting in dyspnea. This dyspnea, if long continued, will result in a suboxygenation blood disintegration and a new attack of asthma.

After a month's freedom from asthma, I test my patients with eggs and meat.

Asthmatics stand operations poorly and are often made worse by them, especially operations on the nose and throat. People who have never had asthma have been rendered asthmatic by operations as shown by the following cases:

Case IX.—No. 1151, February 8, 1921, Mrs. K. W., Buffalo, N, Y., aged forty, weight 158 pounds, tonsillitis and quinsy four or five times a year, especially spring and fall for ten years, in bed ten days with attacks. Tonsils removed three years ago. Showing an increase in temperature nearly every day since the tonsils were removed with severe leucorrhea, and for the last four weeks has had asthma and bronchitis. In bed six weeks before consulting me. On February 12th the patient still had a temperature of 99.8°, with hemorrhoids and an acid stool. February 15th there was no asthma but still an increase in temperature now and then. The patient began to recover rapidly and had no asthma until March 7th when she had a mild attack of dyspnea with a temperature of 100°, while visiting in Jamestown. After this the patient continued to recover and has had no trouble since. This patient also had lumbago for two winters after her tonsils were removed.

"Hertzberger declares that none of the current theories explains asthma while some actually contradict the facts observed" (3). This statement is positively true of the authoritatively established nerve reflex spasm theories.

The blood origin of asthma is most convincingly demonstrated by its frequent complication or alternation with urticaria, eczema, pimples, boils, ab-

scesses, rheumatism, migraine or leucorrhea. This is shown by the following case:

Case X.—No. 1349, April 3, 1924, Mr. W. F. G., Buffalo, N. Y., aged fifty-four, weight 158 pounds, married thirty years, two children living. The patient had boils at the time of the consultation and stated that he had them when a boy and that he had had three hundred boils in the last three years. Had had asthma for the last three years in a severe form. Two years ago was home for seven months and not able to do anything. A year ago he was home five months.

The patient continued to have boils after he began treatment and in October, 1924, he had an abscess on his thigh that put him in the hospital where it was lanced and drained. He did not have any distressing asthma with this abscess and his asthma did not bother him much for about six months. This time the asthma came from a boil in the nose, following a boil on the neck. This nasal boil infection went from the nose to the larynx, trachea and bronchi, making his asthma troublesome, but he did not stop work until April 30, 1925. He now began, as I advised, rest in bed, castor oil and mineral oil, starvation, blood rechemistration, treatment, with hot poultices, hot foot baths, hot drinks, saltpetre stramonium belladonna smoke inhalations, gin. As this attack of asthma was unusually long and distressing, the patient and his family requested something more for relief. After talking over the hypodermic side of relief, we decided to first try a weak solution of cocaine (five grains to the ounce) to be inhaled from a nebulizer. Accordingly, I left him a prescription for the solution. I also added to his blood rechemistration a five grain tablet of ammonium chloride and a five grain tablet of sodium bicarbonate to be taken every hour, followed by a cup of hot water. The next day when I called I found that his asthma had been so much benefited by the ammonium chloride and the sodium bicarbonate that he had not used the cocaine atomizer. His recovery from this date was satisfactory. Asthmatics, when possible, should be educated to control their attacks, without resorting to hypodermics of any kind.

The following case shows how the disintegration of the asthmatic's unstable blood may alternate between a nonfebrile reaction and asthma or a febrile reaction and no asthma:

Case XI.—No. 824, August 30, 1916, Mr. J. S. A., Java, N. Y., farmer, aged thirty-five, weight 153 pounds. This patient had asthma since twelve; extremely bad last year, worse from August to March. Sits up at night with attacks. Pneumonia at twelve, followed by asthma. Had fever spells three or four times every fall and winter, temperature 102° to 103° with chills which confined him to bed for a few days with each attack.

Mother's mother had had asthma all her life, died at the age of eighty-four. His mother had had asthma ten years ago, one winter, still a little asthmatic at times, aged fifty-nine. One brother had asthma for five years, mostly winters, aged thirty-two.

This patient is still under observation and during these nine years he has worked hard on his farm and has had practically no asthma except in the fall of the year from August to January, when the night ground gases, with the chilly, heavy, dewy nights, would disintegrate his blood with either a nonfebrile reaction and asthma or a febrile reaction and no asthma. Some falls it would alternate between asthma and fever.

On November 18, 1918, the patient had a spell of fever resembling typhoid. On consultation with Dr. C. M. Smith, of Johnsonburg, N. Y., we pronounced it typhoid. His chest was full of râles during the typhoid, but he did not have any asthmatic dyspnea. This sick spell lasted until January 26, 1919.

On September 9, 1919, patient reported to my office, stating that he had worked hard all summer with no asthma except for the last two weeks when he began to have some asthma alternating with spells of fever, which began about August 20th with chills. On October 3rd, patient had no asthma and was feeling fine.

On March 31, 1920, patient stated that he had had no asthma all winter, except reminders when walking outdoors on cold days. Had influenza in January, in bed for one week, no asthma with it, but some rise in temperature. August 23rd, patient had no asthma all summer. October 7th, the cold nights with their heavy dews and ground gas accumulations had given him a few periods of rise in temperature, but no asthma until the last few days, then only reminders.

January 24, 1921, patient had a good winter with no asthma. April 14th, patient had a good spring. August 23rd, patient had no asthma all summer and worked hard. A few August reminders. October 20th, patient had no asthma until October 15th and 16th when he had chills, followed by rise in temperature. After this he had some asthma.

August 31, 1922, Patient put in a good winter and summer with no asthma until five days previously. November 6th, patient had a good summer and fall with no asthma. Had some rheumatism in his right elbow.

September 11, 1923, patient had a good summer and winter with no asthma. On August 25th, he began to show an increase in temperature and was in bed a half a day at a time for one week. He stated that he often worked while having a temperature. Temperature 102° to 103° at times. Had some asthma between fever spells. December 10th, patient had had no asthma and was feeling fine.

February 15, 1924, patient had had no asthma. September 19th, patient had no asthma all summer, but a little asthmatic since September 1st. Chills September 17th, 4 p. m., followed by rise in temperature. No asthma with this. Temperature in office was 99.8°. November 29th, patient had no asthma.

March 2, 1925, patient had had no asthma all winter.

This man's farm of a hundred acres is located in a craterlike valley, looking as though it had once been a lake. A little creek runs by his house and barn. His farm makes an excellent pocket for night, ground gases to settle in. In October, 1920, while out on a hunting trip, I stayed all night at his house on a chilly, windless, heavy dew night with a black frost and in the morning the ground gases were evident. At this visit I advised my patient to heat his house with a furnace, sleep upstairs, and put in a gas filtering ventilator.

Rackemann asks, "Why do not many more individuals exposed to dusts such as orris powder and

horse dander become sensitized? There must be in certain individuals, and luckily not many, a tendency to develop hypersensitiveness. The nature of this tendency is unknown" (4).

It is evident that this tendency is due to instability of the blood or in other words, allergy of the asthmatic is due to instability of the blood. Grain, seeds, animals, hay and straw generate hematolytic gases.

The asthmatic can easily tell whether it is a dust or a hematolytic gas that gives him asthma by simply using the United States Universal gas mask to be alternated with a sponge or wool dust mask. If the dust mask does not protect him and he is protected by the gas mask, it is a hematolytic gas that is causing the trouble.

If a summer coryza victim or an asthmatic can work with a grain threshing machine, a hay press, or around animals in the winter, with no regard to his diet, without having coryza or asthma, it demonstrates that the cause of his coryza or asthma is neither dust, gas nor food, but a heat retention.

Summer coryza victims and asthmatics must be educated to guard against heat retentions or heat humidity hematolytic crises on hot, windless, humid days by either resting in a shady, cool room with a fountain and an electric fan, riding in a covered vehicle with open windows or exercising vigorously enough to produce a free perspiration. Some should migrate to a cooler location. Heat, humidity, high blood viscosity or concentration of the blood through loss of fluid by perspiration should be guarded against by the drinking of plenty of water, according to Flinn, Barbour and Engel (5).

Gas is the most immediate essential chemical of our existence. We can live but three minutes without oxygen gas, three days without water and thirty days without food. Some of the agents that disturb or contaminate our atmospheric oxygen are overpopulation, combustion, destruction of forests and atmospheric vibrations from explosions, engines and airplanes.

There are now accumulated enough scientific facts concerning asthma to enable the general practitioner to treat cases of uncomplicated asthma as indicated and to educate them to live without incapacitating asthma.

The Technician Problem*

JOSEPH C. BOCK, Chem.E., Ph.D.

Milwaukee, Wis.

The ever increasing importance of chemistry in medical diagnosis has made analytical work of a more complicated type a necessity. The larger and some of the more progressive smaller hospitals have established separate chemical laboratories and have put competent biochemists in charge.

It is the purpose of the present paper to discuss briefly a problem which has arisen contemporaneously with the necessity for chemicodiagnostic work, a problem which presents a grave danger in many respects: the problem of the inadequately trained technician in the chemical laboratory. Some hospitals, on being confronted with ever increasing requests for blood analysis, may seek the easiest way in solving the problem. They decide to equip a chemical laboratory. The usual procedure then consists in building a few shelves in a neglected corner, haphazard buying of a minimum of equipment and employing a chemical technician. This technician is supposed to do complicated chemical work, mostly of a microanalytical nature; go through procedures which require training of the highest type and perfection. Not only that, but quite frequently the results must be obtained in a minimum amount of time and must be absolutely dependable.

In order to acquire a semblance of preparation for the work, the person chosen tries to go through some sort of training. This instruction is usually obtained by either doing routine work in some commercial clinical laboratory or by taking a course in a technicians' training school. The candidate very often has not even completed a high school course. His or her knowledge of chemistry and physics is almost nil and the general education entirely insufficient. In spite of this meagre foundation, the student technician is put through a laboratory course and is expected to acquire the technic of some of the most delicate analytical procedures in an absurdly short period of time.[1]

It must be admitted that this technician will be able to get results of some sort. This can be explained by the fact that most of our blood analytical methods are of the colorimetric type. Unless the worker skips several lines of the printed directions, a color will develop in the solution under examination and a "reading" will be obtained. The technician makes a report and not infrequently will even be asked to interpret the results.

This whole situation constitutes a grave menace. There is no one to check up, to tell when and where a mistake has been made. The mere fact that duplicate results show agreement does not vouch for the correctness of the findings; it probably means noth-

*From the Department of Physiological Chemistry, Marquette University School of Medicine.

[1]One training school lists a course in blood chemistry requiring forty laboratory hours and teaches special urine analysis, inclusive of colorimetry, cryoscopy, and other essentials in the same amount of time.

ing more than a duplication of the same error. Very often the solutions are bought from some supply house, are used until gone, without any attempt of standardization or assay being made. The short training period and the complete absence of knowledge of the necessary fundamental sciences prevent the technician from judging if one or more of the reagents are fit to work with or not.

The question necessarily arises how the problem could be approached. The solution may present difficulties in hospitals of small capacity and limited means. We admit that many of these institutions cannot afford to employ a graduate biochemist to take charge of the laboratory. A well trained technician, however, can do the routine work, but only when under the rigid supervision of a competent chemist familiar with the task in its fullest scope.

Undoubtedly the opinion will be advanced that the pathologist or some physician could just as well supervise and control the chemical laboratory work. It must be admitted that there are a number of physicians capable of doing it, but those are few and far between.

How many practitioners could make a N/50 acid or an alkali if given an analytical balance and the necessary chemicals and glassware? How many could standardize a burette or pipette? In fact, how many could define the term normal sulphuric acid? Comparatively few medical men are thoroughly familiar with the chemical composition of the blood in health and disease, the importance of the variations and deviations from the accepted normal contents and their diagnostic application. We know of a case where a fake report of a blood sample was shown to several physicians. This report gave the number of milligrams of urea nitrogen about ten per cent. higher than the nonprotein nitrogen, but not one noticed the obvious nonsense.

While the diagnostician must necessarily keep himself informed of the advancements made in biochemistry, he cannot be expected to be an expert in chemicoanalytical work. He would not attempt to operate an x ray machine or an electrocardiograph himself, but neither would he accept a röntgenogram made by a person who learned to manipulate a few switches and to develop photographic films by taking a forty hour course.

The fact will be mentioned that we have successfully employed technicians in pathological work. This comparison is not to the point. The final diagnosis in this case is made by the pathologist, either resident or visiting, and not by the technician. If a section is cut too thick or is faulty in some other respect, if a staining process has been carried out in a negligent manner, the pathologist will be able to tell that something is amiss. As mentioned before, chemical processes are apt to give some sort of a result in most of the cases, and only competent supervision will prevent errors that may be of the gravest consequence, or may even mean the loss of a human life.

Unrelated Disease a Factor in Diphtheria Virulence

DWIGHT M. LEWIS, M.D.

New Haven, Conn.

It is common belief in medical literature and in laboratory procedure, that virulence of organisms once lost in the human is not regained. As the basis of the view that diseases spread from some previous case of the disease, observations at variance with that view are of importance in the explanation of both endemic and epidemic frequencies of respiratory diseases.

Epidemiological observations over a number of years have shown me that whether diphtheria or scarlet fever, there was evidence that virulence was gained when a carrier of the disease (other than the convalescent carrier), passed through an attack of some other specific respiratory disease.

In a recent article (1), I showed that nasal diphtheria carriers could gain a positive virulence after an attack, for example, of measles, chickenpox, scarlet fever, whooping cough or mumps. Instances were given where a donor had a negative virulence while the recipient during or following the other specific diseases mentioned, had a positive virulence. After years of search for the direct proof where all the factors occurred in the same individual, I have recently, for the first time, met with such an occurrence. The instance was as follows:

Mary S., aged four, was found to be a nasal diphtheria carrier on May 28, 1925, when the origin of a missed case of the disease in her brother, Frank, aged three, was sought. Both the original mixed field and pure fishing cultures from Mary gave negative virulence tests while those for the throat culture from Frank were positive. On June 13, 1925, measles developed in Mary.

When she was convalescent, on June 28th a request for a virulence on the culture taken on that date was made. Both mixed field and pure fishing cultures were returned as having positive virulence.

CONCLUSION

It is my opinion and experience that the cyclical frequencies of respiratory diseases are dependent on the tides of carriers with virulence regained through immediately preceding unrelated respiratory disease. Weeks, months or even years of freedom of cases of any one disease may thus be followed by its reappearance.

Myxomembranous Colitis

CHARLES GOLDMAN, M.D.
Brooklyn, N. Y.

Synonyms.—Mucous colitis, myxorrhea coli, mucomembranous colitis, catarrhal colitis, mucous colic, and chronic intestinal catarrh.

Definition.—Mucous colitis is a disease of the intestines in which mucus is passed either alone or with feces in jellylike masses or in the form of a tough pseudomembrane resembling a tapeworm, and sometime as a complete cast of the bowel (1).

Etiology.—The disease may occur at any age and is found in males as often as in females. The condition may be brought on by abnormal endocrine function, infection of the intestines from focal lesions in the teeth, tonsils, appendix, or gallbladder, from ptomaine or chemical poisoning, from mechanical obstruction, and faulty metabolism.

Pathology.—Opportunities to perform necropsies upon patients suffering from myxomembranous colitis are so rare that little is known of its pathology. The mucosa may be normal, but usually the mucous glands and follicles are distended with mucus. There may be congestion or ulceration of the mucosa. The mucus is tenacious and stringy, and is sometimes expelled in the form of a cast of the bowel. The cast contains degenerated epithelial cells, leucocytes, and mucus, but contains no fibrin. These casts are often mistaken for intestinal parasites.

Symptoms.—In mild cases the passage of thickened mucus several times daily without discomfort may be the only symptom. In more severe cases there may be loss of appetite, mental depression, gas distention, abdominal soreness, headache, nervousness, colic, constipation alternating with diarrhea. The disease accompanying or causing the myxomembranous colitis may give added symptoms.

A brief history of the case from which the mucous cast shown in the illustration was obtained follows:

CASE.—Mr. G., aged forty-two years. After excessive indulgence in alcoholic drinks he complained of a peculiar sensation in the abdomen which began in the epigastrium and became localized in the cecum after two days. The patient was obstipated. Four days after the onset of the symptoms he complained of severe abdominal pain in the region of the descending colon. A proctoscopic examination at this time revealed a mass in the sigmoid resembling a tapeworm. On the fifth day, accompanied by a quantity of blood and excruciating pain, the cast was passed.

Treatment.—The treatment is directed toward the removal of the cause if found, the removal of the retained mucus, and the relief of symptoms. It is well to tell the patient that a long course of treatment is necessary for a cure.

The diet is varied to suit the needs of the patient but must be sufficiently nutritious to sustain the patient. The least amount of food supplying the greatest nutrition with the least residue is best.

General treatment should consist of supervising the hygiene of the patient. The medicinal treatment should be directed toward toning up the nervous and muscular system by strychnine and arsenic, and bromides as a sedative if necessary; relief of pain dur-

ing attacks of colic by belladonna and codeine; arrest of fermentation and diarrhea by salol, salicylate of bismuth, ichthyol, and the sulphocarbolates; relief of

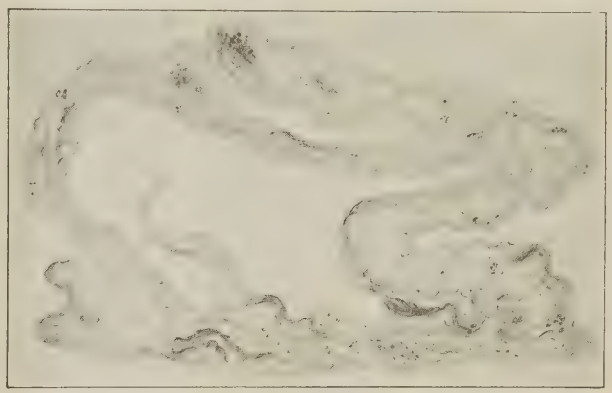

FIG. 2.—Cross section of mucous cast of the bowel showing mucous, degenerated epithelial cells and a few leucocytes. Note the lumen.

constipation by the use of mineral oil and bile salts.

Local treatment consists in preventing an accumulation of mucus by irrigations of the colon once a

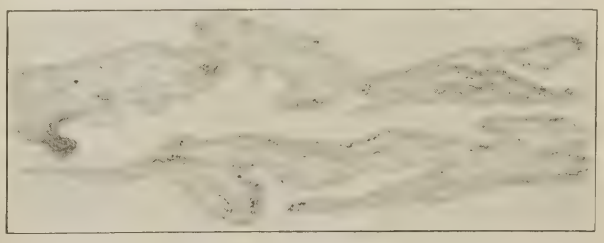

FIG. 3.—Longitudinal section of mucous cast of the bowel.

week or more often if necessary. Several gallons of water at 100° F. should be used. The bag should not be raised more than a foot or two above the

patient who is placed on the left side for the first gallon of water, and then on the back or in the knee chest position.

Surgery.—A pathological appendix or gallbladder should be removed, or any other source of infection should be cleared up, and any cause of constipation which can be remedied surgically should be attended to. The advisability of cecostomy or ileostomy is still debatable.

Sarcoma of the Bladder

WILLIAM ROSS JAMIESON, M.D.
El Paso, Texas

Sarcoma of the bladder is a rare condition, as is evidenced by the literature on the subject, which is mostly confined to reports of single cases. Geraghty (1) found two cases of sarcoma in 180 of bladder tumors. Albarran studied eighty cases of vesical malignancy finding two cases of sarcoma. Watson (2) found fifty-two sarcomata in 863 bladder tumors collected from literature, while Gardner (3) gathered seven in 369 cases. Yet the Mayo Clinic reports only one case in 262 treated at that institution. Such discrepancies in statistics leads to the suspicion that all the tumors reported were not sarcomatous.

AGE

This form of vesical tumor appears in early childhood but more frequently in adult life. Mixter (4) found only eight cases in children in eight hundred cases of bladder tumor. Munwes reports ninety-eight cases of bladder sarcoma with fifteen per cent. occurring in children under ten years of age. With so great a preponderance of sarcomatous tumors in the very young, Munwes suggests an embryonal origin of genitourinary tumors in children and Mixter agrees with this view.

Sarcoma of the bladder, whether in old or young patients, is exceedingly malignant. In consistency, these tumors are soft and friable, occasionally villous. They infiltrate deeply the surrounding tissues, the bladder walls, seminal vesicles, rectum, prostate, ureters, and even the bony pelvis.

SYMPTOMS

The principal symptom is sudden painless hematuria, which according to Geraghty occurs in sixty-two per cent. of vesical sarcomata. The amount of blood may vary from a blood tinged urine to a profuse hemorrhage. This may stop as suddenly as it began, appearing again in from a few hours to years. Diet and exercise have no influence on the appearance or amount of blood passed. The disappearance of the blood from the urine may often lull the patient into a sense of false security from which he is rudely awakened by learning later through examination by a careful diagnostician that his case is malignant and inoperable. The amount of hemorrhage is no indication of the size of the tumor, as small ones may bleed profusely while larger ones bleed little. Blood in the urine is a signal of trouble along the genitourinary tract. Therefore the source of any genitourinary hemorrhage should be diligently sought for.

Pain is the symptom next in importance. This can be divided into two classes: first, that due to involvement of the pelvic nerves in the malignant process, and second, that due to cystitis and ulceration of the bladder. The latter is much more common than the former. Added to this is frequency of urination

Fig. 1.—Hydronephrosis and dilatation of ureter.

tending to make the patient's life miserable through loss of sleep.

OBSTRUCTION AND RETENTION

When the growth attains a size sufficient to obstruct the urethral orifice, difficulty in urination even to the point of complete retention ensues. If the growth surrounds or involves the ureteral orifices, intermittent or complete hydronephrosis or pyonephrosis, if infection occurs, is the result. In the latter condition, it is only a matter of time when death takes place from uremia.

CONSTITUTIONAL

The combination of frequent and prolonged hemorrhages, absorption of pyogenic toxins from the ulcerated bladder and infected kidneys produces its effect in the general depression of health with resultant cachexia.

The following case presents some features of interest:

Case.—Male, aged twenty-nine, Mexican, laborer, entered the City and County Hospital on February 5, 1925, complaining of inability to urinate and swelling of the abdomen which had existed for a month. He gave a history of having had gonorrhea several years ago, but was apparently cured. His personal history was negative, except that two years before he had been struck in the perineum by the handle of a shovel. Examination showed a fairly well nourished

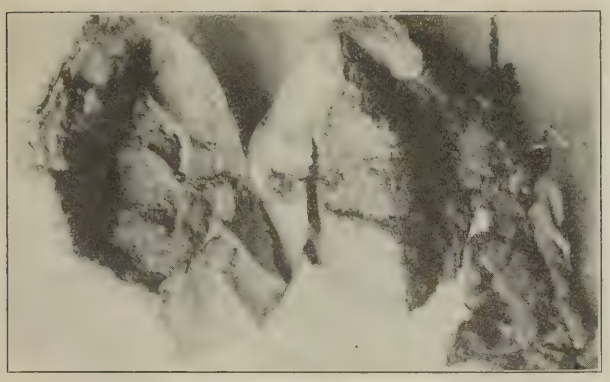

FIG. 2.—Sarcoma of the bladder.

male with sickly yellowish skin and facies indicative of pain. In the midline of the abdomen there was a large very tense mass extending from the symphysis to three inches above the navel and outward to the flanks. Percussion note over tumor was flat. Palpation elicited some pain. In view of the history of gonorrhea a tentative diagnosis of urethral stricture was made. A number 20 F. sound was passed which met with some scar tissue in the posterior urethra, but did not prevent passage of the instrument to the bladder. The sound was withdrawn and a soft rubber catheter inserted. This was followed by a spurt of exceedingly foul smelling urine which ceased abruptly. The catheter was pulled out and a clot was noticed hanging to it. Under novocaine one half per cent. anesthesia, a suprapubic cystotomy was done. It was noted that the bladder wall was extremely thick and gave considerable resistance to the knife. On entering the bladder a stream of foul purulent urine was expelled with great force. The bladder incision was enlarged and the organ found to be packed with clots of various sizes and in various stages of decomposition. Evacuation of the clots was followed by profuse bleeding which was not controlled by hot irrigations, but finally yielded to packing with gauze. Wound was closed.

The following day he said he felt better. Gauze was withdrawn without return of the hemorrhage. On the 11th, a persistent hiccough developed, and he complained of heaviness in his chest. A sample of blood for estimation of urea was taken. Temperature was persistently subnormal. On the 17th he complained of swelling of the penis and a periurethral abscess was found and evacuated of about thirty c. c. of pus with a urinous odor. Blood urea nitrogen 218 mgs. per 100 c. c. During his stay in the hospital he had great difficulty in emptying the bowel. Examination showed a tight constriction beginning just beyond the internal sphincter. It would not allow the index finger to pass. The patient quickly declined and died on the 22nd.

REPORT OF POSTMORTEM EXAMINATION

Postmortem held on February 23, 1925, by Dr. Willis W. Waite.

The body was that of a Mexican man, slender, fair nutrition. Surgical wound in the midline, above the symphysis, about ten cm. long. Body had been embalmed when examined. There were no external marks of violence and the examination was limited to the abdomen.

On section, there was no excess of fluid and apparently no adhesions outside of the pelvis. Pelvis was filled with the bladder, which had been opened surgically.

The bladder was thick walled, bound down with adhesions and completely filled the pelvis and was exceedingly difficult to remove. On removal, it was made up of a heavily indurated wall which on section was of a grayish white color and quite firm, and it was so large that it encroached on the rectum to which it was adherent.

Kidneys were enlarged due to dilated pelves. The left kidney also contained a large dilated sac—apparently a portion of the ureter.

The mucosa of the stomach was intensely congested. Palpation of the organs showed no lesions and were not removed.

A diagnosis of carcinoma of the bladder; hydronephrosis; chronic nephritis was made.

Microscopic examination showed a growth made up wholly of spindle cells quite closely packed. The microscopic diagnosis was a spindle celled sarcoma.

Benign Tumors of the Anus and Rectum

CHARLES J. DRUECK, M.D.
Chicago

(*Concluded from page* 651)

Descourdes (9) reported eighty cases of intestinal myomas of which sixteen were in the rectum. They are nodular in shape and may be pedunculated or imbedded between the submucous and muscular layers, and may project into the bowel lumen or grow outward away from the rectum. If the myoma is small and imbedded in the rectal wall it may be mistaken for a scirrhous cancer. They may, however, grow very large. In the case reported by Descourdes, the tumor was the size of a cocoanut, presented at the buttock and made sitting difficult.

Cullen (10) reported fifteen cases of adenomyoma of the rectovaginal septum. Of these five were his own, the remainder were distributed as follows: Stephens five, Jessup two, Lockyer two, and Nadel one. Kellogg (12) has reported a case occurring in his own practice. Yeomans (13) reported one case.

The histological origin of these neoplasms is not always clear. Their most frequent site is on the anterior surface of the rectum in the triangular space back of the body of the uterus or the cervix, below the peritoneum and from which situation it may extend anteriorly into the uterus, laterally into one or both broad ligaments or backwards into the rectum. A given tumor may spread in all of these directions and fix all of the pelvic organs into one mass. The new growth may project as a definite nodule into the lumen of the bowel, pushing the mucosa before it or it may spread out laterally around the gut as an annular band. Myomas have also been found in men in the space between the bladder and rectum.

Symptoms.—The symptoms depend upon the size of the growth and the structures involved. If small and free in the rectovaginal septum or posteriorly in the hollow of the sacrum, they may exist without causing symptoms.

1. Profuse and painful menstruation is complained of by nearly all women. Cullen (10) reports a patient who suffered from painful floodings despite having a panhysterectomy two years before.

2. When the broad ligaments are involved pelvic neuralgia of the rectum and sacrum is distressing as a result of pressure on the nerves. This symptom is especially severe during the congestion incident to menstruation.

3. If the tumor projects into the lumen of the bowel, obstruction to defecation may occur, although when the mucous membrane becomes fixed it congests and dysentery and rectal hemorrhage are complained of.

Vaginal examination presents a thickening of the vaginal vault which may be nodular but is usually diffuse as the tumor spreads out laterally and resembles the inflammatory exudate of pelvic cellulitis. The vaginal mucosa covering the mass is puckering and bluish if the tumor is adherent to the vaginal wall. In the case reported Cuthbert Lochyer (11) there were blue points like varicosities in the mucous membrane.

Rectal examination.—The tumor can often be more clearly defined per rectum than by the vagina. The growth frequently involves the rectum and the mucous membrane is fixed and puckered.

Diagnosis.—The diagnosis is difficult and is to be differentiated from 1, polypus; 2, scirrhous cancer; 3, pelvis cellulitis.

A careful and thorough microscopical examination is necessary in every case. Primary carcinoma of the vagina is very rare.

Treatment.—1. Where small discrete nodules exist in the triangular space between the vagina and rectum they may be dissected out through a vaginal incision.

2. Where the growth invades the cervix or uterus an abdominal hysterectomy should be performed.

3. If the growth glues the rectum and uterus together, the uterus should be freed on both sides. The uterus may be carefully dissected free and by incising the vagina anteriorly and laterally the uterus and rectum can be lifted up out of the pelvis while a section of the anterior wall of the rectum is removed.

4. If the mass spreads around the rectum and narrows its lumen the bowel must be resected.

Of all tumors of the bowel those at the rectosigmoidal juncture are the most difficult to remove. In some cases the operation can be completed through the abdominal incision. If, however, a considerable portion of bowel must be sacrificed, the danger of infection, peritonitis and fecal fistula are very grave. In such instances it is far safer if the sigmoid is sufficiently long to mobilize the portion of bowel containing the tumor, close the abdomen and complete the operation by the perineal route, doing a Genu-Tuttle or similar extirpation of the rectum, preserving the sphincter ani and forming a new rectum from the sigmoid which is sewed to the anal margin.

CONGENITAL SACROCOCCYGEAL DEPRESSIONS, CYSTS AND SINUSES

In the median line in the sacrococcygeal region there occurs infoldings of the skin, which are congenital in origin, the result of a bud of epithelium turned under the external integument during fetal development. Because of the findings of tufts of hair within these pockets they are spoken of as pilonidal cysts. This condition is quite common although it may not cause any annoyance.

Désprès and Lannelongue say that one third of all new born infants have some degree of these sacrococcygeal deformities but that when adult life is reached only three per cent. of the people show this abnormality.

Of the three congenital abnormalities here considered, viz., depressions, sinuses and cysts, the depression is by far the most frequent. The sinus is much less frequent. It may be as much as two inches long with an orifice perhaps so small as to admit but a fine probe, or it may be large enough to be mistaken for the anus. This external opening is usually over the tip of the coccyx but it may be higher even over the lower end of the sacrum. Rarerly it lies between the tip of the coccyx and the anus.

Males present the great majority of cases, Criffon and Archibald (14) had two females in thirty-one cases. Lynch (15) reported fifty-one cases and all were males.

In some instances only a pit, depression or dimple exists as in Fig. 7, while in other subjects an epidermoid cyst exists which may later break down or become infected and a discharging sinus result as in Fig. 8. These different clinical conditions are but varying degrees of the same anomaly.

Etiology.—Many theories have been advanced to explain these cysts and sinuses. McNealy (16) in an exhaustive paper quotes from Keibel and Mall as follows:

"If one examines a sagittal series through an embyro eleven centimetres long it is seen that the extreme tip of the cord lying in the tail anlage has been closed off to form a simple epithelial sac. The lumen of the cord above this point becomes obliterated and there results a slender solid strand of nervous tissue which we know as the filum terminale. The epithelial sac becomes the vestige medullaire coccygien, the development of which is described by Tourneaux (*Precis d'embryologie humaine,* 2d. ed., 1909, pp. 348) as follows: At the beginning of the third month the neural tube still extends to the extreme end of the vertebral column into the tail bud and its slightly enlarged tip is closely united to the deep layers of

the skin. Toward the end of the third month the spinal column, developing faster than the soft parts, draws along the part of the neural tube that is adherent to it and whose extreme tip remains attached to the skin. As a result of this unequal growth the terminal or coccygeal portion of the neural tube becomes bent in the form of a loop, the more deeply situated limb of which is attached to the posterior surface of the coccyx (segment coccygien direct) and the other more superficial limb extends obliquely from a caudal and ventral position to one more dorsal and cranial (segment coccygien reflechi). During the course of the fourth month the more deeply situated limb, the segment coccygien direct, atrophies and disappears, while the more superficial one, the segment reflechi, continues to develop into the fifth month and gives origin to cell cords or cell masses which contain cavities, lined either with prismatic or pavement epithelium; these are vestiges medullaris coccygiens or paracoccygiens. These structures from the sixth month on suffer a progressive atrophy, but it is possible to recognize traces of them up to the time of birth."

McNealy concludes that these depressions and fistulæ are due to the more rapid growth of the soft parts causing traction of the ligamentum caudale upon the vestiges coccygiens which is intimately attached to the deep layers of the skin.

Lannelongue (18) believes that the persistence of a fetal connection between the external skin and the lining of the medullary canal causes the fistula, and that when the fistulæ are later constricted cysts arise. Mallory (19) from the study of sections through the sacrum and coccyx of various aged embryos is inclined to agree with Wette (20) that the site of the fistulæ and cysts is due not to insufficient development of the mesodermal masses but to delayed closing of the medullary canal or incomplete obliteration of a fetal canal.

Pathology.—The cysts are generally found immediately beneath the skin but may be found much deeper. Wette reported one cyst found in the spinal canal. Usually the cyst is adherent to the skin or actually a part of the skin at the point of epidermal invagination, and when dissected out they will be found to connect with the spinal column by a fibrous band.

The walls of the cysts vary in thickness, according to the amount of connective tissue present.

There are two types of cysts. The first type is due to dilatation of the epithelial sacs which constitute the vestiges medullaris coccygiens. In this type of cysts are found nerve cells. A second type of cyst results from dilatation of the deep part of a fistula, or from occlusion of a fistula near its exit. It is possible they may be formed by the skin anlage being entirely cut off from the surface and existing in the soft tissue.

Some of the cysts and fistulæ are lined with stratified squamous epithelium showing hair follicles and rudimentary sweat and sebaceous glands. When these sacs or fistulæ are opened hair, sebaceous and skin debris and cholestrin crystals are found and sometimes pus if suppuration has taken place.

Symptoms.—The cyst, although always congenital, may remain a long time in a dormant state causing little or no disturbance unless accidentally injured or irritated, when it may inflame and suppurate, causing, if left irritated, an infected ulcer, the surrounding parts are red and swollen and sometimes riddled with sinuses.

The surgeon is not consulted until pathological changes have taken place. The patient gives a history of irritation followed by one or more abscesses in the region of the lower end of the spine. Upon examination and separating the buttocks, one finds in the median line over the coccyx a small fistulous opening. There may be several fistulous openings. A probe introduced penetrates upward for one or two inches toward the sacrum, Fig. 9. On laying the sinus open, it is found to terminate in a small pocket perhaps an abscess cavity containing a coil or tuft of hair. The presence of this hair at the bottom of the sinus has always excited interest and curiosity.

Differential diagnosis.—When the depressions (pits) only exist they may escape notice altogether but these recesses are very difficult to keep clean and become filled with epithelial debris and dirt, which causes chronic irritation and infection and finally abscess. When seen at this stage, and it is rarely found earlier, it may be mistaken for a rectal sinus. If suppuration has existed for considerable time a complete fistula may exist or the retained septic products may burrow widely through the soft tissues and rupture on the surface elsewhere. McNealy reports a case with widely separated fistulous openings. Other cases have been mistaken for osteomyelitis of the sacrum or coccyx.

Where multiple fistulæ exist, the sinuses should be injected with bismuth paste and the various ramifications identified with a röntgenogram picture or fluoroscope examination.

Spina bifida are situated as a rule directly in the median line and should warrant careful investigation to make a certain diagnosis. Various mixed tumors may originate from these vestiges coccygiens and also dermoids are described as arising from the hind gut or mesenteric canal, but these cannot be considered here.

Treatment.—The simple pit or depression causes no inconvenience and does not demand treatment. Cysts and fistula which are not infected may be excised under local anesthesia. A wide infiltration is necessary of the skin and fascia. A careful dissection is necessary and therefore a complete circle of anesthetic wheals must be made. An elliptical incision is then made around the sinus. The encircled mass is then grasped with toothed forceps and lifted out of its bed as the incision is carried underneath. Every particle of the infolded epithelium must be removed or a fistula will result. The incision made wide of the sinus is carried well beneath the mass that all of it may be removed. If no infection is present the wound should be immediately closed with interrupted black silk sutures. The sutures pass through the skin, fatty subcutaneous tissue and beneath the base of the cavity. Only in this way can perfect approximation and obliteration of the cavity be effected. The sutures are tied over a roll of gauze. The wound is then dressed with collodion to further protect it against any possible infection from the anus. If infection occurs, the sutures should be immediately removed, and the wound allowed to heal by granulation. In other instances where the sinus has

several ramifications a general anesthetic is to be preferred to allow careful thorough dissection. This also applies where the sinus extends deeply or where it or the cyst are attached to the coccyx. Sometimes when the patient presents himself the cyst or sinus is acutely inflamed or abscessed and immediate complete removal is not possible without infecting the wound. Such cases should be dressed open and allowed to granulate.

Bloodletting

CHARLES GREENE CUMSTON, M.D.

Geneva, Switzerland

Abandoned by the profession on account of its abuse in former days, the practice of bleeding is, I believe, fortunately being resorted to again. The indications for letting blood are governed more by the symptoms than by the affection. Foremost among these may be placed venous hypertension, with orthopnea, cyanosis, oliguria and edema. These signs are the index of primary or secondary cardiac insufficiency. In renal processes bloodletting is indicated when myocardial failure arises, compromising renal elimination when the severe accidents occur; also in cardiac asthma and acute pulmonary edema during crises of hypertension. Frequently, this indication may necessitate arteriotomy.

It is an impossibility to estimate, *a priori,* the amount of blood to be let; the symptoms to overcome and the patient's condition are to be taken into account. From six to eight hundred cubic centimetres of blood may be regarded as an average amount. Generally a single bleeding will suffice as the object to be attained is to pull the patient through a dangerous situation.

Physiological data do not permit one to predict the effects of one bleeding. Whether it be the amount of blood to be let without danger, the effect produced on the pulse, respiration and changes arising in the figured elements of the blood, the presence or absence of thirst, it will be found that opinion differs from what physiologists tell us, because we are dealing, not with normal, but with pathological states. The phenomenon of thirst, in particular, is ordinarily observed following hemorrhage, but is not met with in subjects presenting edema. After the blood has been abstracted the economy calls upon fluids of the cells to repair the loss when the subject is normal and therefore thirst ensues, but when the patient is edematous he does not experience thirst for the simple reason that the network of connective tissue contains reserves of fluid which reestablish the humoral equilibrium.

It must not be supposed that the arterial pressure will invariably be reduced by bleeding as this is decidedly not the case. When the pressure is reduced by bleeding it has been noted that three factors are in play: 1, the importance of the bleeding; 2, the rapidity of the bleeding—which in some case produces accidents comparable with shock; 3, an individual decrease of normal tonicity of the vasomotors. Let it also be said that to reduce arterial pressure at least one litre of blood must be let.

From the clinical viewpoint the uselessness or even untoward effects of bleeding in permanent high blood pressure are to be noted, while the withdrawal of blood in hypertensive crises—with reserve in absence of accidents and contraindicated in cerebral hemorrhage—is decidedly indicated in paroxysmal dyspnea and convulsive nervous accidents. In these cases, by relieving the paroxysmal hypertension bloodletting will cause all the symptoms to subside.

Contrary to what takes place in the arterial system, withdrawal of blood always reduces the venous pressure. In asystolic subjects bleeding, instead of reducing diuresis, activates urinary elimination. By causing the fluid of edema to enter the circulation it removes a barrage; by increasing the differential pressure it increases cardiac energy, while by lowering the venous pressure it reduces stasis, especially in the kidneys. The rapidity of the flow of blood is increased and if the kidneys are not the seat of important lesions the output of urine will vary in proportion to that of the blood. This polyuria causes the edema to melt away, but while in some this takes place immediately, in others it is both slow to arise and is irregular.

Bleeding prepares the patient for the action of cardiac stimulants by reducing the barrage in the pulmonary circulation, kidneys and tissues. By causing the extravasated fluids to enter the blood stream, bleeding removes the barrage offered by the capillaries just like drastic medications. But bleeding alone in some cases may relieve the symptoms of asystolia, its action being similar to digitalis. By reducing venous hypertension, cardiac tonicity is increased and, on the other hand, by provoking endosmosis of the fluids of the edema it produces the same effect as digitalis in the first phase of its diuretic action.

Bleeding does not reduce azotemia; it is, however, indicated in eclamptic manifestations and uremia. We now know that in nervous uremia the convulsive accidents depend upon chloruremia and arterial hypertension and not upon nitrogen retention. Therefore, if bloodletting acts heroically in convulsive uremia it is because it overcomes the hypertensive crises and depletes the acute cerebral edema.

Functional Diabetes

HENRY J. JOHN, M.D.

Cleveland, Ohio

Cases of diabetes may be divided into two contrasting groups; those with what may be termed functional diabetes, in which carbohydrate tolerance can be increased by proper treatment over a sufficient period of time, and those in which, no matter what treatment is employed for whatever length of time, the carbohydrate tolerance cannot be increased beyond a certain fixed limit. The latter type of the disease may be termed anatomical or destructive diabetes, since the degeneration of a certain portion of the islands of Langerhans has progressed beyond the possibility of repair, functional repair at least, whether or not any change of the cells can be demonstrated histologically.

Functional diabetes on the other hand represents an early stage of the disease, in which the degeneration of the island cells of the pancreas has gone on only to the first stage, to the hydropic degeneration of the beta cells. During this stage the change in the cells apparently is still reversible and by prompt and proper intervention, much of the tolerance for carbohydrates can be regained.

When the process has gone beyond the stage of hydropic degeneration of the beta cells, to a slight or a more extensive degree of fibrosis of the islands of Langerhans, by proper treatment the destructive process may be arrested, but the lost tolerance cannot be restored.

Clinically it was noticed years ago, that after a maximum degree of carbohydrate tolerance has been established in hospitalized diabetic patients, as time goes on, some will be able to assimilate increasing amounts of carbohydrates and maintain a normal blood sugar level, and the sugar free urine, whereas, in other cases, the carbohydrate tolerance never increases beyond the degree attained at the hospital. In the second group of cases any increase in the carbohydrate intake means an increase in the blood sugar content, and glycosuria, and the patient has to revert to the diet prescribed at the hospital at the time of his discharge.

Recently at the Physiatric Institute, Copp and Barclay (1) showed that in dogs in which a diabetic status had been established but in which the damage to the islands of Langerhans had not progressed beyond the hydropic degeneration of the beta cells, the process was still reversible. In these cases not only did a functional improvement result when a proper diabetic regimen, with insulin if needed, was instituted, but the cells of the islands appeared to be restored, as is shown by the photomicrographs published by these investigators. Such an early stage of diabetes therefore can be considered a functional diabetes since at that stage only the function of the pancreas is disturbed. If the process is allowed to go on, however, there will result a permanent, partial or complete cessation of the pancreatic function, according to the number of islands which have been permanently impaired. This study by Copp and Barclay is significant because it offers pathological evidence which is in harmony with our previous clinical experience.

An interesting report illustrating the reversibility of the degenerative process in the pancreas in early diabetes in man has recently been published by Boyd and Robinson (2). The authors describe the case of a boy nine years of age, who had had diabetes since he was two years old. His life had been maintained by treatment but his general condition was getting worse and he was able to utilize only fifteen grams of carbohydrates. He weighed but thirty pounds and his height was only thirty-nine inches. In December, 1922, insulin and an increased diet were prescribed as a result of which "his tolerance for carbohydrates trebled in the year" and it was possible to reduce the insulin from ninety to thirty units per day. "From a chronic invalid in 1922 he became the leader of the gang in 1923. He was killed by fracturing his skull when sleighriding. He lived only about three hours after receipt of the injury and an immediate postmortem examination was made."

In the examination of the pancreas, the authors found none of the degenerative anatomical changes commonly found in diabetics, but did find changes which were interpreted as a regeneration of the cells of the islands of Langerhans. Some cells were definitely hypertrophied and there was an apparent increase in their number, a point which should give much hope to the diabetic patient. The most im-

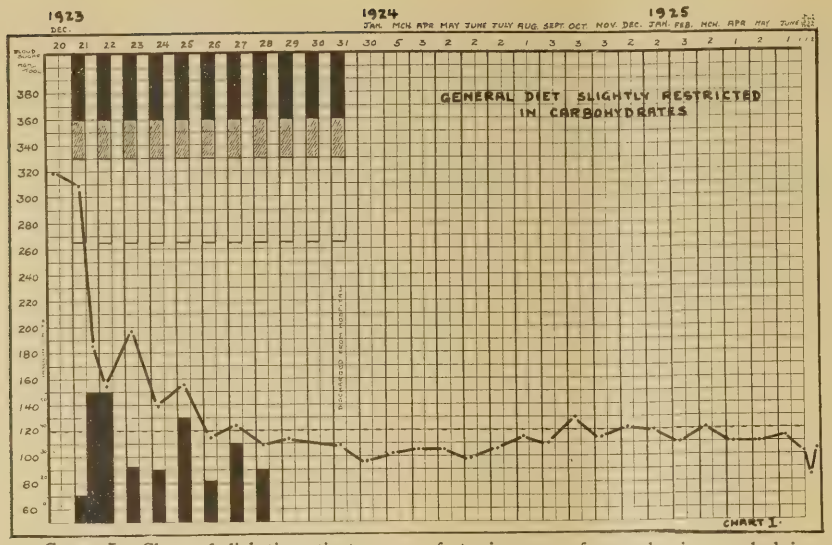

CHART I.—Chart of diabetic patient, a man forty-six years of age, showing marked improvement as manifested by the discontinuance of insulin and the maintenance of a normal blood sugar level over a period of two years. The long columns in the upper part of the chart indicate the diet, the black portion representing the carbohydrates, the shaded portion, the proteins, and the blank portion, the fats. Each square represents twenty grams. The columns in the lower part represent the daily insulin dose.

portant finding was that the beta cells of the islands of Langerhans which are believed to be most concerned in carbohydrate metabolism and are the first cells to be destroyed in severe diabetes were normal and increased in number. That is, by means of insulin and a proper diet the strain placed on the already functionally deficient cells of the pancreas was lifted and their normal functional capacity was resumed.

The authors state further that the distribution and prominence of the islets in the peripheral portions of the pancreas very strongly suggest the formation of new islands.

These findings are in accord with the reports of hypertrophy of the islands of Langerhans which have been made by various authors (3, 4).

Clinically we observe the results of the above processes quite frequently, but it has been difficult to secure confirmatory pathological data. Such an accidental occurrence as in the case cited above, therefore, is of great value since it provides an interpretation of our clinical experience.

It would appear that the progress in the following cases, in one of which insulin was used, while in the other only dietary management was employed, can be explained only by the assumption of such a regeneration of the islands of Langerhans as has been described.

CASE I.—The patient was a man forty-six years of age, with a familial history of diabetes. He complained of excessive urination and loss of weight. His family physician had prescribed a diet of cream, grapefruit and buttermilk, but during the preceding four months he had lost thirty-nine pounds in weight, and his symptoms were continually getting worse. When I first saw him his blood sugar was 318 mg. per 100 c. c. and he had a glycosuria of ten per cent. in his urine.

He was placed in a diabetic hospital, on a diet consisting of carbohydrates, gms. 100; proteins, gms. 60; and fats, gms. 128; making a total of 1800 calories. On the first day he received two doses of insulin of ten and fifty units respectively.

The insulin therapy was continued for eight days; the blood sugar fell to the normal level on the fifth day and on the eleventh day the patient was discharged from the hospital. Ever since his discharge he has been on a fairly liberal diet, even eating pie and cake occasionally. As is shown in Chart I, his blood sugar has remained normal for two and a half years, during which period he has been working hard at his trade, and has felt quite well.

On the basis of the considerations offered above the only way in which such a sequel can be explained is by assuming that we were dealing with an early case of diabetes at a stage when only functional changes—hydropic changes of the beta cells—had taken place in the islands of Langerhans, so that these cells as in Copp and Barclay's dogs reverted to a practically normal status. This regenerative process was no doubt promoted by the insulin, but even if only a low diet had been used, the same end result would undoubtedly have been accomplished. This case demonstrates also the fact that insulin, once used, need not be continued throughout the rest of the patient's life, a bugbear which oppresses the laity and even some of the profession.

CASE II.—The patient was a lad nine years of age, with no familial history of diabetes. He had had

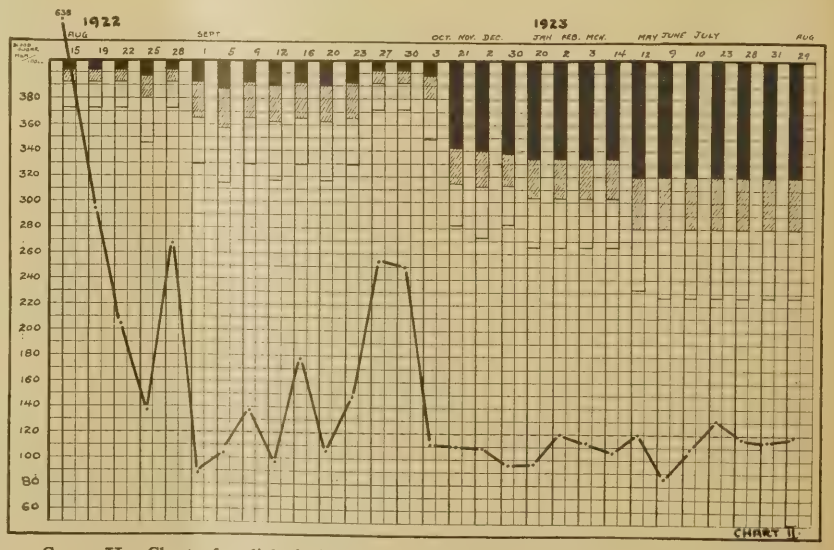

CHART II.—Chart of a diabetic boy nine years old showing maintenance of normal blood sugar level on gradually increasing diet.

measles, whooping cough, and scarlet fever, and tonsillectomy and circumcision had been performed at the age of four. He was brought in by his parents because of a socalled rundown condition.

Six weeks before he had begun to lose his appetite and to be nauseated. During these six weeks his temperature had been elevated and his condition had been diagnosed as glandular fever by the family physician.

He was first brought to the Clinic on August 15, 1922, when a glycosuria of 3.3 per cent. was discovered; the blood sugar content, four and a half hours after a meal, was found to be 638 mg. per hundred c. c. of blood, and acetone was present in the plasma.

The blood sugar level fell promptly on a low diet, but rose again the last of September, when the diet was further reduced, after which the blood sugar fell to the normal level where it remained for nearly a year in spite of an increase of the diet up to two thousand calories per day. The progress of this patient is shown in Chart II.

This case shows a comparatively rapid gain in tolerance in a young boy, after the blood sugar had been restored to normal by a regulated diet.

This, like the preceding case, is an example of the functional type of diabetes, in which the degeneration of the cells of the islands of Langerhans had not progressed beyond the possibility of restoration.

Although functional diabetes presents a very encouraging outlook for physician and patient alike, it does not mean that when a case of diabetes has once been demonstrated to be of the functional type and has been kept in control for a year or two, that such a patient is permanently "safe." He is not! We still have to stick to the old rule: once a diabetic, always a diabetic. The patient must never forget that he has diabetes, even though it be in a latent form, and I always feel uneasy when a patient increases his diet of his own accord, as often a splendid clinical result is spoiled by such an unwise procedure. There is a point of least resistance and when this is reached the tolerance fails and it is then too late for further regeneration of the damaged pancreas. It is thus far safer to keep a little below the limit than to overstep the dietary boundary.

The following case in which a splendid functional result was secured at first, but in which the tolerance broke down two years later, is cited as a warning to the overenthusiasm alike of the patient and of the physician:

Case III.—This patient was a boy of eighteen, who came to see me on July 14, 1922. He had had no childhood diseases, and there was no family history of diabetes. An appendectomy had been performed in 1911. He complained of weakness and a socalled dopy feeling which had lasted for about three weeks, during which time he had lost nineteen pounds in weight. Glycosuria had been discovered three weeks before I saw him. When I first saw him his blood sugar, two hours after a meal, was 333 mg. per hundred c. c., he had a heavy glycosuria and there was a large amount of acetone in the urine. The blood Wassermann test was negative.

From the protocol, in Table I, the progress of this patient can be followed. In two weeks a glucose tolerance test gave the result shown by curve 1, on

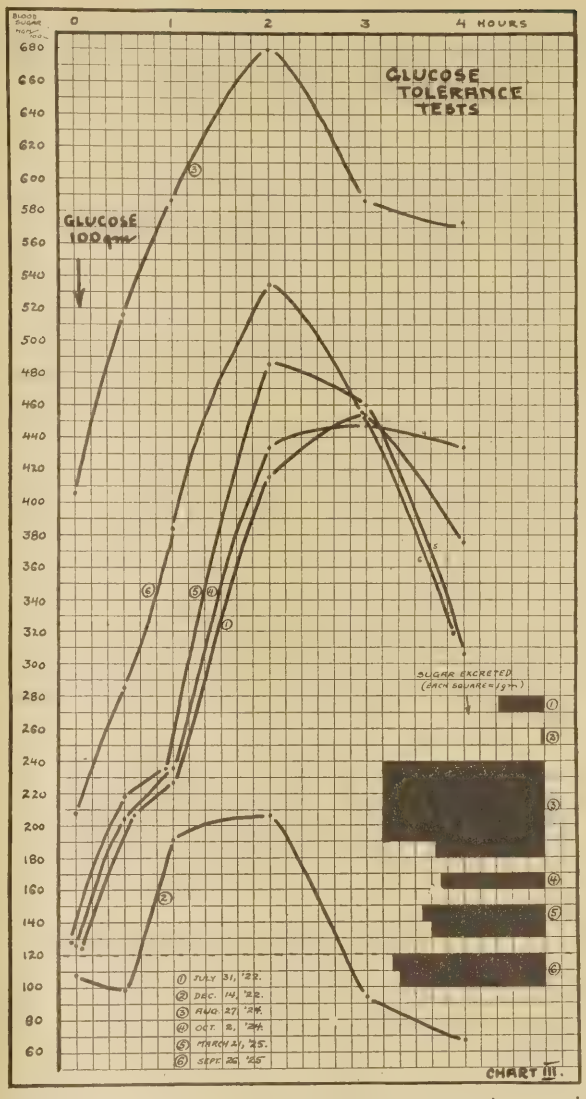

Chart III.—Repeated glucose tolerance curves, covering a period of three years, in the case of a diabetic boy, eighteen years of age. Sugar excretion is indicated in black columns at right.

Chart III. Although the fasting blood sugar was normal, this is a definitely diabetic curve and moreover, during the test the patient excreted 2.92 grams of sugar in the urine. Later the diet was increased to 2600 calories and the subsequent blood sugar estimations remained normal for five months, so it looked as though the diabetic condition was about cleared up. I made another glucose tolerance test which gave a curve suggesting a mild degree of diabetes (curve 2, Chart III), and only 0.18 grams of sugar was excreted. Thus, everything indicated that this was a functional type of diabetes which, under a proper diabetic regimen had nearly subsided.

In May, 1923, the patient went to Europe and I warned him to watch his diet carefully, but the native wines and beer proved too tempting to be resisted. When he returned in August, 1924, I did not at first suspect that the blood sugar level was high as he told me then that he had adhered closely to the prescribed diet, and I learned what had happened only after taking the glucose tolerance test, the result of which is shown in curve 3, Chart III.

The height of the curve and the excretion of 56.73

grams of sugar, together with a marked lipemia and acetonemia, showed what destructive changes had occurred. I placed the patient in the hospital and began using insulin and the blood sugar gradually returned to the normal level. Another glucose tolerance test (Curve 4, Chart III) gave about the same type of curve as curve I, but the patient excreted more sugar, namely 6.35 grams. At the end of the test I administered twenty units of insulin, as in the subsequent tests, and four hours later the blood sugar was 152 mg. per hundred c. c.

Glucose Tolerance Test (See Curve 6, Chart III)					

Five months later the next glucose tolerance test was performed, giving curve 5, which was about the same as curves 1 and 4, but the sugar excretion was 14.3 grams.

Six months later another glucose tolerance test was performed, giving curve 6, which is nearly the same as the previous one, but the sugar excretion was 18.4 grams. This patient had apparently reached a stationary stage and perhaps never will be able to regain the tolerance he once had, although he manages to keep a normal fasting blood sugar level, and is able to work hard.

This case emphasizes the dictum quoted above: once a diabetic, always a diabetic. It demonstrates that no matter how good a functional result may seem, it is best to think twice before risking carelessness in eating. This boy had been able to take care of a good diet, was able to do any amount of work and to keep a normal blood sugar level; now he can still take care of a good diet, but only by taking insulin. He realizes now that his dietary indulgence wasn't worth while, but unfortunately it is too late. In this case, then, we assume that the degenerative changes in the cells of the islands of Langerhans have progressed beyond the hydropic degeneration of the beta cells and have entered upon the stage of fibrosis or permanent dysfunction.

CONCLUSIONS

1. There is apparently a mild type of early diabetes in which there is but a slight change in the islands of Langerhans, which we may call functional diabetes. This has been observed clinically for many years; and has been produced experimentally by Allen, Copp and Barclay, and others who have demonstrated a hydropic degeneration of the beta cells in such cases.

2. Under proper treatment much restoration of function and a histological restoration of the islands of Langerhans may take place.

3. In spite of apparent restoration of function, these cases will break down under undue strain.

4. Once the presence of a diabetic status of any degree has been established, adherence to the prescribed diabetic regimen should never cease; and the physician should maintain a continuous control.

Rate of Elimination of Ingested Sugars in Phlorhizin Diabetes.—H. J. Deuel, Jr., and W. H. Chambers (*Journal of Biological Chemistry*, August, 1925) studied the rate of sugar excretion in fasting dogs rendered diabetic by phlorhizin, using fructose, glucose, galactose and lactose. The rate of elimination of extra glucose after feeding sixteen gm. of fructose is practically identical with that of glucose itself. The results with galactose suggest a more rapid excretion of extra sugar. With lactose the extra glucose produced is much less and its excretion lasts over a much longer period of time, the extra glucose not having been completely eliminated twelve hours after its ingestion. The amount of extra glucose eliminated in the urine when glucose, galactose, and fructose were fed represents a practically quantitative recovery.

The Relation of the Endocrine Glands to the Teeth in Rickets*

WILLIAM G. WARD, M.D.
Boston, Mass.

My paper will be on the relation of the endocrine glands to the teeth, especially in rickets, one of the most obvious diseases of civilization.

I have chosen rickets for its endocrine dental pathology which, I know, you are not familiar with because endocrinology is not, as yet, a prescribed course in the dental and medical schools of this country. (The University of Pennsylvania in its graduate department has a chair of endocrinology presided over by Professor Sajous.)

I shall not go deeply into the reported etiology of rickets except to state that many theories have been advanced on its causation.

Some observers assert that it is caused by a deficiency of the fat soluble vitamine A; others to food containing too much starch; to overeating; to acidosis which causes decalcification of the bones; to infection, and lastly, heredity.

I believe it to be due, entirely, to an endocrine imbalance, and agree with those who believe that heredity is the cause, the inheritance of endocrine dysfunction from a hypoendocrinic mother.

The strain of pregnancy unmasks the latent endocrine insufficiency. The less marked the defensive reaction of the thyroid, parathyroids, pituitary, thymus, gonads and suprarenals the more virulent and unrestrained appear to be the effect upon the formation and resultant pathology of the teeth in the child. Acidosis is only a symptom of rickets, not its cause.

Rickets has been styled by many writers as the English disease because of its greater prevalence in the British Isles. Glisson and his contemporaries gave it the name "rhachitis, the spinal disease," because an affection of the spine appeared so often in their cases. Probably this was due to a hypothymic state.

Rickets show one all the endocrine dental pathology desired. Besides the bone lesions referable to the skull, ribs, spine, long bones, wrists, ankles, etc., we find delayed dentition. A child of two years of age may have only a few milk teeth, perhaps the incisors and a molar or two.

The teeth in this disease rapidly decay, frequently down to the gums where they appear as ragged black stumps. Of course, this same condition may occur in any wasting disease of infancy to some extent.

As in all wasting diseases, especially so in rickets, we find a calcium deficiency always present and quite commonly a lowered phosphorus content also. The phosphorus content of the blood is increased by giving extracts of the pituitary, thymus and the ovary.

It has often occurred to me that osteomalacia has many characteristics found in rickets and I have for some time believed that it was a late form. Calcium is an absolute necessity in all bone formation, the teeth included, because they are also bony structures.

The endocrine glands prominently identified in the development and protection of the teeth are the thyroid, parathyroids, pituitary, gonads, suprarenals and thymus. The other endocrine glands are so closely interrelated with the above that they, too, enter into the development also, but we know less about their action at the present time. I have often thought that the spleen is a calcium metabolic stimulant, preparing suitable calcium salts for presentation to the bloodstream and the impoverished body cells, changing the basic to an ionic salt similar to the action of the parathyroids.

The endocrine glands which we know govern the calcium content in our bodies are the parathyroids, thymus, thyroid, pituitary, suprarenals and gonads. The parathyroids, thyroid and thymus all have the same effect upon growth. They also act together as calcium retainers in our bodies. This leads one to realize that these glands are functionally and embryologically related. Unless these lime binders are activating normally there is nothing to hold and utilize the lime in the body, thus the teeth suffer along with the other bones.

In cases of rickets and marasmus the thymus gland has been found in an atrophied condition. The relation of the parathyroids to rickets was first suggested by Erdheim, in 1914. The fetus depends entirely on the maternal thyroid hormone. When the child is born its thyroid contains no iodine. Iodine is not taken up by the thyroid until several weeks or months after birth.

Some investigators consider the thymus function to be entirely a detoxicant. When we have a hypothymic function the toxins are not neutralized and this is a direct cause of rickets. Many clinicians think it advisable to use thymus gland therapy in all cases of rickets as a lime binder. The parathyroid glands are the most important lime binders in the body. The recent work of Vines in England and Collip in Canada has opened up a greater understanding of these little glands.

Collip states that overdosing with the active hormone which he has discovered may push the rise of blood calcium to a condition of hypercalcemia that may even become fatal.

Besides calcium deficiency in rickets, what other conditions do we find? Why this lack of lime salts? We find that the parathyroids, thyroid, thymus, pituitary, suprarenals and gonads are tired out in the mother and are underactivating. This hypostate accounts for the hypocalcemia. There is not sufficient lime to form good strong healthy teeth in the embryo.

A rapid excretion of lime and phosphorus from the body takes place when the glands which are the lime binders are not functioning and, singularly as it may seem, one of the first bony structures to be affected by this loss to the blood are the teeth.

In rickets it would be interesting to know what proportion of the cases of pluriglandular insufficiency are due to congenital syphilis. It is said that it is as high as three per cent. but I doubt if it is more than a half of one per cent. The pituitary, gonads and suprarenals are the most commonly infected and the thyroid not so frequently, in congenital syphilis.

*Lecture delivered to the Interns of the Forsyth Dental Infirmary, June 18, 1925.

Let us remember that the eruptive time of the teeth is a thymicopituitary function; the position in the jaw is a thyroid-thymus-pituitary-suprarenal-gonadal function; the quality of the teeth is a thyroparathyroid-pituitary function and the resistance to decay and infection is a thyroparathyroid function.

Rapid decay of the first teeth always indicates a thyroparathyroid hypofunction. Conclusive evidence suggests that there is a close relation between the thyroid and the parathyroids.

How does the resulting imbalance of the parathyroids, thyroid and thymus occur to cause the child this deficiency of lime in the teeth with the resulting rapid decay? From the mother during the prenatal period and soon after birth is the most obvious answer. Most of the mothers of rickety children are found to be in a hypoendocrine state. They are usually hypothyroid, hypoparathyroid and hypothymic. Frequently the suprarenals are also in a hypostate.

These mothers start before, at the beginning of pregnancy or soon after, with an underfunctioning thyroparathyroid condition. This condition results in an increased compensatory activity of the pituitary and thymus glands. These glands, overworked as they are by their added duties, soon play out, become exhausted, and henceforth are underactivating. Thus the resulting hypostate of the lime retainers of the body. When they should be normally active they become abnormally inactive. Lime that should go to form bone and teeth is lacking in a normal amount with a resulting deformity and decay.

The fourth week the embryo is about a quarter of an inch in size, the thyroid, parathyroids and thymus can be identified. The first or milk teeth begin to form at this time. A mother with a hypofunctioning of her parathyroids, thyroid and thymus cannot retain enough lime in the blood to form good strong teeth and thus her baby's eruptive time is long delayed, possibly two years or more elapses. She cannot supply sufficient lime for her infant's bones and softening of the general osseous system ensues. The bones are deformed and the teeth are delayed in their eruptive time and decay rapidly follows their eruption. That is what you find in rickets.

The embryonic thyroid, parathyroids and thymus immediately begin to functionate but are influenced entirely by the chemical substances of the mother's hormones until birth takes place. The products of the mother's glands affect the embryo's. There is a constant interchange of these substances from mother to embryo. If the mother's internal secretory glands are underactivating the embryo's glands are immediately affected the same way. If the mother's thyroid gland is hypofunctioning the embryo's thyroid is hurt, causing the various chain of thyroid syndromes to follow throughout the child's whole lifetime. Given a hypothyroid mother and we we will also have a hypoparathyroidism and a hypothymic condition associated because these three glands are so closely related, functionally and embryologically. When these glands are in a hypostate they are, as I have stated before, unable to retain lime enough in the body for normal use and this condition will cause dire results because the child's bones, teeth and nervous system will be affected by this lack of calcium.

Rickets is found in ninety-two per cent. of premature and twin infants. This shows an undoubted hypocalcemia at birth.

A hypothyroidism in the mother affects the thyroid in the fetus with resulting distortions, stunted growth of the bones and teeth and an arrest of development of the child as a whole.

A hypoparathyroidism in the mother will set up a train of deficiency syndromes in the child such as rickets; it will also set up a train of nervous symptoms in the child which will, perhaps, mar its future life. Undoubtedly the convulsions which are so common in rickety children are due to a hypoparathyroidism which sets up a hypocalcemia.

A hypothymic state in the mother will set up in the fetus a train of deficiency syndromes such as delayed dentition and an irregularity in the placement of the teeth in the jawline. A hypothymic condition causes a loss of phosphorus to the bones including the teeth.

Rickets is surely a deficiency disease but not due to diet but principally to a deficiency of the endocrine glands which control the retention of calcium salts in the body.

Since Bretonneau's time (1778-1862) codliver oil has been used extensively in rickets as a cure, first in France and then universally. I believe the results from its use are probably due to its iodine content which activates the thyroid to a more normal action. The fat soluble vitamine A it contains may exert a stimulating force on the endocrine glands which are the lime binders of the body. Phosphorus added to codliver oil enhances its activity.

The latest treatment of rickets advocated by many recently is the use of the x ray, the violet ray, the quartz lamp and sunshine. Beneficial results are frequently reported.

A peculiar fact is that all these rays are direct stimulants to the endocrine glands and perhaps that is the reason why benefits are derived from their use. The rays cause considerable hypertrophy of the glands thus treated which is shown microscopically to be a true hyperplasia of the parenchymatous tissue. The rays also raise, by their stimulation of the glands, the blood calcium.

Besides a diet of fresh vegetables, hygienic conditions and fresh air, I use a very reasonable endocrine treatment and get good results in rickets by giving a combination of the parathyroids with thyroid and calcium lactate. Calcium is more readily absorbed when parathyroid is added to the combination.

It is suggested that if the combination mentioned above is used in all hypoendocrine states found in the prenatal period we will not find so many cases of rickets in the baby later and the baby's teeth will be less likely to decay rapidly.

To counteract the secondary anemia so frequently found in rickets, I give a combination of red bone marrow and spleen, two and a half grains of each three times a day.

Endocrinology of the teeth is slowly being worked out by many investigators and later, I have no doubt, it will be as an open book. I believe the time ripe for the dentist to give more heed to the endocrine glands in their relation to the teeth for I am positive that endocrinology will help us in preventive dentistry.

Report of a Series of Hypertrophied Thyroids Treated With Radium*

J. COLEMAN SCAL, M.D.
New York

The treatment of this series of cases was started in 1923 and announced in the 1924 bulletin of the Otolaryngological Clinics of the Beth Israel Hospital in New York City. Since then almost two years have elapsed allowing sufficient time for their observation to warrant a fair report.

A goitre or thyroid enlargement is usually a simple parenchymatous hypertrophy, occurring mostly in young adults. In such cases there is usually a uniform enlargement of the gland which develops gradually and without pain or other symptoms. Its first indication is seen in the increasing size of the neck and tightness of the collar. If it still continues growing, dyspnea results from pressure upon the trachea.

There may be little or no goitre showing in the neck, yet an x ray of the thorax will reveal an intrathoracic goitre pressing on the trachea. Such a condition may account for a shortness of breath—dyspnea—and sometimes is mistaken for asthma.

This enlargement of the thyroid gland is most likely a true hypertrophy which occurs in response to a demand for an increased supply of internal secretion. In most cases where hypertrophy starts, it continues increasing in size beyond its physiological limit and becomes pathological. In these cases early medical treatment is often effective. This consists in satisfying the demand for increased thyroidal secretion from an external source, so that the gland is able to rest, and undergoes diminution in size. Where this condition is neglected and becomes longstanding fibrous tissue develops, and medical treatment has little or any effect at all. In such cases the application of large doses of radium has shown encouraging results. In cases of goitre, where the ordinary treatment has proved useless, and where operations are advisable, radium should be tried.

*From the Otolaryngological Department of Beth Israel Hospital.

In goitre containing cysts or adenomata, radium has been found to be less effective. Some diminution in size may follow its application as a result of atrophic changes in the gland substance itself. In such cases the operation for the removal of the cystic or adenomatous thyroid is simplified by the previous application of radium. Where the thyroid is very large, occurring in middle age or in very elderly persons, and usually of the cystic variety, radium is practically useless. Operation here is advised where the enlargement is a repulsive deformity, and then only when no hypothyroidism exists.

In exophthalmic goitre there is usually present a colloid degeneration of the thyroid gland. This produces a group of symptoms including tachycardia, palpitation, nervousness, tremor, loss of weight, and general weakness. These symptoms resemble those coming on after feeding an excessive amount of thyroid gland, and are brought on by an overproduction of thyroid secretion, which is thrown into the blood stream. Medical treatment is directed for relief of symptoms and is usually regarded as having no effect on the duration of the disease. X ray treatment has been discarded as it is too destructive, and liable to result in hypothyroidism. Operative procedure has been discouraging. Radiotherapy in this condition has been satisfactory.

The radium is applied to the neck over the thyroid screened first by a brass container, and then by a wooden block about six centimetres in depth. A total exposure of 250 millicurie hours is obtained by applying one hundred milligrams of radium for two and a half hours.

This application is repeated in two weeks, and the subsequent treatments four weeks apart. The number of applications given depends upon the basal metabolism and the clinical signs. Where the thyroid

Fig. 1.—Case II Fig. 2.—Case IV Fig. 3.—Case V Fig 4.—Case VI

No.	Name	Age	Sex	Variety	Duration	Symptoms	Basal Metabolism	No. of Treatments	Dose	Results
1	E. H.	37	F	Parenchymatous	3 yrs.	Thyroid size of an egg. Urine and Wassermann negative. No exophthalmic symptoms.	+8	8	100 mg	Marked improvement. Thyroid much smaller.
2	R. G.	32	F	Cystic	1 yr.	Enlarged neck, painful swallowing.	+26	4	100 mg	No result apparent.
3	I. A.	19	F	Exophthalmic	11 yrs.	Slight exophthalmic signs. Pulse 96, eyes somewhat bulging; marked tremor at fingers. Nervous.	+21	5	100 mg	Marked improvement. Neck much smaller. Pulse 86. Not so nervous.
4.	S. B.	41	F	Parenchymatous	12 yrs.	Blood pressure 200 / 90. Pressure on trachea, choking sensation.	+ 8	8	175 mg	All pressure symptoms on trachea gone. Neck much smaller. Both lateral lobes of thyroid markedly diminished in size.
5	I. W.	26	F	Cystic	6 mos.	Pulse 80	+ 9	4	100 mg	No result apparent.
6	L. S.	34	F	Exophthalmic	8 yrs.	Thyroid size of orange, getting larger. Nervous. Eyes bulging slightly. Face flushed. Marked tremor of fingers. Pulse 96.	+ 9	4	200 mg	Slight improvement in exophthalmic signs but none in size of thyroid.
7	M. K.	14	F	Parenchymatous	7 mos.	Not yet menstruating. Thyroid enlarged. No exophthalmic signs.	+6	8	(3- 50 mg (2- 75 mg (3-100 mg	Excellent result. Thyroid just visible.
8	A. W.	27	F	Exophthalmic	10 mos.	Neck enlarged, left eye bulging. Pulse 90, nervous. Marked tremor of fingers.	+4		100 mg	Exophthalmus lessened. Left eye does not bulge as much. Nervousness markedly lessened.
9	J. R.	37	F	Parenchymatous	6 wks.	Frequent pain in throat. Neck continues to swell. No exophthalmic symptoms. Pulse 72.	+2	4	200 mg	Thyroid slightly smaller.
10	S. E.	45	F	Exophthalmic	1 yr.	Neck continues to swell. Pulse 120, Von Graefe sign present. Nervousness. Tremor.	+56	4	200 mg	Feels better. Nervousness improved. Size of thyroid same.
11	D. H.	25	F	Exophthalmic	4 yrs.	Lost 30 lbs. in two years. Nervous and dizzy. Sleepless. Eyes bulging. Pulse 120. Marked tremor at fingers.	+63	7	175 mg	Good result. Eyes do not appear to be as prominent. Feels much better. Nervousness markedly lessened.
12	P. L.	25	F	Cystic	4 mos.	Nervous. Right side of neck enlarged.	+8	4	(1-30 mg (1-40 mg (1-60 mg (1-75 mg	No improvement noted. Dose too small. Did not return for treatment.
13	R. B.	36	F	Cystic	2 yrs.	Very nervous and easily excited. Repeated flushes and chills.	+8	7	100 mg	Symptoms improved but did not return for further treatment. Thyroid not smaller.
14	E. W.	17	F	Adenomatous	3 yrs.	Neck enlarging past three years. Otherwise no other complaint.	+4	7	100 mg	No improvement noted. Neck same size.
15	S. S.	36	F	Exophthalmic	4 yrs.	Lost 35 lbs. in past four years. Pulse 96, rises rapidly. Suffers headaches and is nervous. Eyes bulging slightly.	+18	2	(50 mg* (100 mg	*Size of thyroid same. Feels greatly improved. Headaches gone. Not nervous. Pulse slower. Did not return for further treatment.
16	Y. A.	21	F	Parenchymatous	2 mos.	Left lobe much enlarged. Right only slightly enlarged.		3	100 mg	Marked improvement. Neck almost normal size. Feels much better. Thyroid enlargement practically gone.
17	F. B.	45	F	Adenomatous	6 yrs.	Operated upon December, 1923, but swelling returned. Has large horizontal scar over neck from incision. Three distinct masses visible and are rather hard.	+31	4	200 mg	No result apparent. Advised reoperation.
18	E. K.	47	F	Cystic	18 yrs.	For past three years neck swelling continuously.	+6	4	100 mg	No apparent improvement.
19	S. W.	27	F	Adenomatous	5 mos.	Neck gradually enlarging.	+9	1	75 mg	No results noted. Did not return for further treatment.
20	R. S.	16	F	Parenchymatous	1 yr.	Thyroid enlarged especially during menstruation.	+7	3	100 mg	Marked improvement. Neck half inch smaller. Did not return for further treatment.
21	S. S.	49	F	Exophthalmic	2 yrs.	Neck enlarging for past two years. Very nervous. Frequent headache and flushes. Marked tremor in fingers. Loss of appetite. Pulse 140 Myocarditis.	+19	7	100 mg	Marked improvement in exophthalmic symptoms. No change in size of thyroid.
22	M. P.	14	F	Parenchymatous	1 yr.	Neck began to swell after removal of tonsils. Centre lobe much enlarged. No exophthalmic signs.		8	100 mg	Marked improvement. Goitre just visible.
23	G. P.	28	F	Exophthalmic	5 yrs.	Cystic mass size of an egg. Right side more tender. Slight exophthalmus. Pulse 120, tremor. Choking sensation present.	+27	5	150 mg	Marked improvement. Tremor gone. Pulse and choking sensation relieved. Exophthalmus improved.
24	I. S.	46	F	Adenomatous	2 yrs.	Large neck. Centre lobe especially enlarged. Nervous and apprehensive. Lost 40 lbs. in past three months.		4	100 mg	No improvement noted.
25	B. R.	34	F	Cystic	9 yrs.	Very large thyroid especially on right side. Slight exophthalmus. Eyes alert, twitching. Pulse 102.	+9	3	100 mg	No improvement noted.

*Was operated upon by Dr. Pool at New York Hospital on February, 1924, but returned to clinic with recurrence of symptoms and return of the goitre.

is greatly enlarged, or where the exophthalmic symptoms are marked, a larger dose of radium is used. This consists in applying two hundred milligrams for two and a half hours, thereby obtaining five hundred millicurie hours.

CONCLUSIONS

My conclusions, derived from the tabulated cases, do not warrant enthusiasm for this method of goitre treatment. The only cases really benefited by the radium were those of exophthalmic goitre. The majority of these improved after the first application. It was gratifying to see the patient with exophthalmic symptoms return in a calm state, nervousness lessened, pulse quiet and slower, with the marked apprehensive look in the eyes gone. In several cases of functional thyroid enlargement in young girls radium was not applied because we obtained good results with the administration of iodine. These cases are not included in our report.

Observations on the Effect of Radium on the Parathyroids*

JOSEPH S. STOVIN, M. D.
New York

A large amount of experimental work has been done recently on the treatment of diseased conditions of the thyroid gland with the x ray and radium. However, a review of the literature on this subject reveals no observations concerning the effect of this therapy on the parathyroids.[1] With this viewpoint, therefore, I assembled some data while working in the Otorhinolaryngological Clinic of Beth Israel Hospital, New York.

The parathyroid glands, usually four in number, are small brown bodies, situated in the meshes of the loose connective tissue forming the outer capsule of the thyroid.

It is the present consensus of opinion that the parathyroids function by elaborating an internal secretion which regulates calcium metabolism (2, 3). The symptoms arising from removal of the glands can be attributed to a condition of hypersensitiveness of the peripheral and central nervous systems, due to a decrease in the calcium concentration of the blood (2). This fact was demonstrated conclusively by Salvesen, who, in an experiment on parathyroidectomized dogs, was able to ward off the occurrence of tetany by the injection of calcium (3).

The character and severity of the manifestations of parathyroid insufficiency vary, according to the amount of parathyroid tissue extirpated. When the removal has been complete, the result is rapid respiration, spasmodic contractions, convulsions, and death (4). In cases where the parathyroidectomy has been partial, the following symptoms have been noted—headache, general weakness, stiffness and tingling in the hands and feet (5), and, finally, the typical carpopedal spasm of tetany (6). Accompanying these, there is invariably a drop in the calcium concentration of the blood (7).

In our clinic, we use the following method in radiating the thyroid cases. The radium is placed in brass containers, which are then wrapped in pure gum rubber and, by means of adhesive tape, are fastened to wooden blocks one inch in thickness. One or more of these blocks are applied securely to the skin overlying the thyroid in such a way that the radium will be on the outside of the blocks. They are left in place from one to three hours, the usual dose for each treatment being two hundred mgs. of radium applied for three hours. Because of the close anatomical relationship between the thyroid and parathyroid glands it is obvious that during these treatments the parathyroids are radiated as well.

TABLE I

8.....	98	98	600
Average.....	92	92	

TABLE II

Case	*Treatment* (mg. hours)	*Blood calcium after treatment.* (mgs. per 1000 c.c)
9.....	250	95
10.....	300	110
11.....	600	80
12.....	300	85
13.....	700	70
14.....	1,050	85
15.....	600	100
16.....	600	85
17.....	1,100	70
Average		86.6

From the series of thyroid cases treated at our clinic, a study in regard to alterations in parathyroid function was made on seventeen patients, who, by the way, represented various types of thyroid diseases. Following irradiation, the patients were questioned closely as to the development of such symptoms as headache, general malaise, stiffness, tingling or actual pains in the extremities (6). None of them had experienced any. Furthermore, the examination of these patients for carpopedal spasm, Chvostek's sign and other evidence of heightened irritability of the nervous system was uniformly negative.

A study of their blood calcium was also made.

*From the Otolaryngological Department of Beth Israel Hospital.

[1]Frey and Kriser have radiated the parathyroids in treating cases of otosclerosis, which they believe is due to a parathyroid insufficiency. While they comment favorably on this method of treatment, they give no report on the immediate effect of the radium on the parathyroids (1).

The method used for the determination of the calcium concentration of the blood was that described by Kahn and Hadjopoulos (8). In this procedure the serum is employed and the normal reading varies from eighty-five to ninety-five mgs. per thousand c.c.

On eight patients in the series, an examination of the blood was made before and after treatment (see Table I). We see that in three cases, the calcium content increased, in three it decreased, and in two it remained at the same figure. The averages of the two groups were identical.

These results were supplemented by the findings in the other nine cases (see Table II). While in this group we have no preliminary examinations to act as checks, we find that after irradiation, no patient had a blood calcium below seventy mgs. per thousand c.c. of serum, and that the average was 86.6 mgs. per thousand c.c., which is well within the limits of normal.

From these observations, the conclusion can be drawn that radium in the dose used, while exerting a therapeutic influence on the size and function of the thyroid gland, does not affect the parathyroids in any appreciable manner.

Pituitary Headache

AGNES SAVILL, M.D.
London

The recent article by Dr. Harrower on headaches relieved by pituitary extract (1) recalled to my memory the following cases, which may be of interest. In each case the preparation employed was, at first, liquid extract, and when the correct dose had been established, tablet preparation of the whole gland were used.

CASE I.—Mrs. B., aged forty-five, first seen early in 1916, complained of headaches increasing in frequency and severity of recent years. A degree of thickening around the neck and shoulders decided me to order thyroid in minute doses; this seemed to increase the headaches. The periods had been irregular and profuse and were unaffected by the thyroid medication which was continued for two months. A trial of pituitary, whole gland, was tentatively begun. Immediately the headaches began to improve; at the same time the thickening of the body, especially of the lower parts, decreased, and the periods became more normal. Pituitary was continued for nearly two years, as the patient found that if ever she omitted it for over a fortnight, the headaches tended to return and to become more violent during the time of the period. Some two years later a small fibroid was discovered and I brought about an artificial menopause by x ray. Pituitary medication has not been required since that time.

CASE II.—A nurse, aged forty-four, first seen in July, 1924, complaining of increasing fatigue and lack of energy during the preceding six months. She had also developed a constant headache, and at times nausea was a troublesome symptom. Rest and a holiday for six weeks had brought about no alleviation of her symptoms. When I first saw her the blood pressure was 165/90; she looked worn out; but the chief complaint was perpetual headache, aggravated at the time of the menstrual period. There were present the thickening round the neck and shoulders, which is so frequent with athyroidism, and also the thickened masses round the lower part of the chest, abdomen and thighs, and the blueness of the breasts and upper arms which is so often associated with deficient pituitary action. She was put on one grain of thyroid and gradually worked up to six grains of pituitary daily. When next seen in October she was another being, slimmer and without headache or nausea. She had observed the symptoms closely and was certain that when she tried to leave off the pituitary the headache tended to return.

She carried on with her work during the winter and gradually left off taking the tablets. In May, 1925, nausea and headaches began to return, and she decided to call on me again. On her resuming the whole pituitary gland treatment the threatened recurrence of her symptoms was at once arrested.

CASE III.—A probationer, aged thirty-three, seen on two occasions in 1921, of obese appearance, complained of severe headaches during the monthly periods. More relief was obtained from tablets of pituitary extract than from any other form of medication. I had not the opportunity of following up or going thoroughly into her case.

I have had several other cases during the past two years, in which headache has been aided by pituitary medication. In these cases, however, as other treatment was being administered concurrently, the relief obtained cannot be entirely ascribed to the use of pituitary extract.

Therapeutic Uses of Parathyroid Gland

With Some Introductory Notes on Its Anatomy and Supposed Function

WILLIAM N. BERKELEY, Ph.B., M.D.
New York

The Swedish original (1) of Ivar Sandström's great work announcing the discovery of the parathyroids is hard to find in New York. The only available account in the library of the New York Academy of Medicine is an abstract in Schmidt's *Jahrbücher* for the same year.

But from this one can easily see that Sandström's work was thorough. He knew exactly what he was about. His comparative studies showed that these bodies are also present in the dog, horse, cat, bullock, and rabbit. In the rabbit, however, he missed the internal pair of glands. These, as A. Kohn (2) afterwards noted, are embedded in the thyroid. Sandström's microscopic studies were also accurate and extensive. He affirmed that the parathyroids are quite diverse structurally from the thyroids, and none of the speculations of later writers that these glands are capable of developing into thyroids has ever been confirmed. He noted that Remak, in 1858, and Virchow, also, had undoubtedly noticed these bodies, and speculated as to their function. He named the glands *Glandulæ parathyreoideæ*. Though German usage also justifies *Epithelkoerperchen* and *Nebenschildruesen,* and Verdun (3) thought that *branchial glands* would be embryologically more appropriate, Sandström's name still survives; and it seems only fair that it should.

ANATOMY

I can only note briefly that in man the glands are usually four in number, two on a side, fitting into notches on the rear edge of each thyroid lobe, and fed by twigs of the upper and lower thyroid arteries. But there is no magic in the positions mentioned or the number four. There may be three, five, six, or eight, and the positions are often anomalous. Fortunately for the incautious surgical operator there are also a number of minute or even microscopic accessory glandules (4) scattered through the tissues of the neck near by. If there be time enough, these are sometimes capable of notable hypertrophy to meet a postoperative demand.

Special students of the anatomy, comparative anatomy, and embryology of the glands, will find extensive bibliographies in papers by Bergstrand (5), Boothby (6), and in the exhaustive monograph by Thompson (7). The last named work contains an almost complete list of authors and papers to the date of publication. Numerous interesting special studies since 1920 will be noted later.

For laboratory parathyroid work the most useful animal is the dog. The parathyroids in this animal are usually four in number, two on a side, attached almost anywhere to the capsule of the corresponding thyroid lobe; and they do not require to be removed as such; a double thyroidectomy is all that is necessary. The accessory thyroids in dogs are so numerous that this operation in a large majority of instances has no essential or lasting effect on thyroid chemistry. The immediate acute symptoms are all due to parathyroid deficiency.

One will not thus get one hundred per cent. of successes. A small percentage of all dogs have minute accessory parathyroids in undiscoverable places. These accessory glands rapidly respond to the postoperative demand, and such dogs remain well, or sicken only temporarily, and later on recover all their previous health, appetite and spirits. But in the majority of instances the untreated animal dies with the typical symptoms of tetany.

If rabbits are to be used, the outer glands are easily removed from their position on the carotid sheath, and if the lower outer third of each lateral lobe of the thyroid be also cut away, the inner glands will be found (under the microscope) embedded in the tissue removed in about eighty or ninety per cent. of the animals operated on. The main trouble with rabbits is the dangerous proximity of the recurrent laryngeal nerve. If this be cut, the animal dies of asphyxia due to occlusive paralysis of the vocal cords.

PHYSIOLOGY

When the glands are all removed from a laboratory animal in the way already described, he recovers from the anesthetic promptly, eats, drinks, and plays for a half day or more, and then becomes characteristically ill. The most notable sign is increased tone of the voluntary muscles. There are fine muscular tremors, and a perceptible increase in muscular rigidity. Voluntary control of the muscular movements is interfered with. Dogs stagger. Rabbits hop a few times, and fall over, suggesting the "festination" of the Parkinson patient. Cats sidle along, every now and then lifting and shaking one foot (wet foot). Rabbits shiver as though with cold. At this stage there may be intermittent convulsions. Young animals are likely to die in a convulsion. Salivation may be marked. The heart beats with the speed of a riveting tool. The breathing is enormously hurried. Dogs are said to have trismus.

There are no reliable reports on temperature. Fever has been reported. Albuminuria is not marked. Hypoglycemia was reported at one time but has been denied by later writers, who say that it does not appear till tetany sets in, when it may be readily explained as due to the excessive muscular activity (8). The animal in later stages lies miserable, emaciated, loathing food, finally stuporous, but often trembling to the end. Death may be early and sudden (convulsions?), or in more favorable instances may be postponed for some weeks. The occasional recoveries may be explained on the principle already mentioned (accessory glands).

These experiments have been repeated in almost every research laboratory in the world. They have been everywhere confirmed except (a good while ago) by Vincent and Jolly, who probably (they used cats) encountered a series of animals with an unusual

supply of accessory glands, and quite recently by L. R. Dragstedt (9). Dragstedt stated that by careful nursing and a milk diet he could get his animals back to normal again, and he concludes that "the parathyroids are not essential to life." Salvesen (10) with two or three dogs asserts that he had the same experience, but he distinctly affirms that the survival was due to the calcium in the milk diet, and that the tetany reappeared as soon as the milk was replaced by a food not containing calcium. Dragstedt's animals in many instances died with the usual symptoms. His protocols are entirely unconvincing. Shapiro and Jaffe (11) conclude that careful nursing and a milk diet merely tide the surviving subjects over the critical period needed for the development of accessory tissue.

In view of all the evidence there is no reasonable doubt that the parathyroids are essential to life.

CHEMISTRY

The physiological chemistry is largely controversial. It can be only glanced at.

In a little known Rumanian medical journal (12) two alert Rumanian scientists, C. Parhon and C. Urechie, published accounts indicating beyond a doubt that intraperitoneal injections of calcium chloride (one half of one per cent.) into sick dogs relieved the tetany. Twenty dogs were operated on, and controls were carefully made at all points. In August, 1907, their discovery was read before the French Congress of Alienists and Neurologists (13).

MacCallum and Voegtlin made the same announcement independently the following year (14). They used intravenous injections. Berkeley and Beebe (15) confirmed the effects of calcium on such dogs, but made the tentative suggestion that such action is pharmacological, and that the spasms perhaps more likely arise from toxic substances in the blood which are normally detoxicated by parathyroid secretion.

A long series of studies has followed. Some authors have found the blood calcium increased and some found it diminished after parathyroidectomy. Some authors have attempted to distinguish between ionized and bound calcium, claiming that only the ionized calcium is diminished. Noël Paton and coworkers (16), at Glasgow, concurred with Berkeley and Beebe in the opinion that calcium had probably only a drug effect. From an immensely long and laborious series of researches the Glasgow students concluded that parathyroid tetany is due to the postoperative appearance in the blood of certain toxic bases, guanidine and methyl guanidine, both of which they stated that they had identified. H. W. C. Vines (17) declared that the gland has two secretions, one of which controls calcium metabolism, and one detoxicates guanidine. I. Greenwald (18) affirms on the basis of a new series of interesting experiments that the chemical methods of Paton and his associates were insufficient for the identification of guanidine in the blood and urine of their experimental animals, and that there is no toxic substance in either blood or urine in tetany—only a calcium deficiency. Professor MacCallum (19) and Professor Paton (20) have each reviewed the recent literature, and respectively reaffirmed the conclusions they previously arrived at. Collip and Clark (21) could not revive with their new parathyroid extract a dog which had received a fatal dose of guanidine.

In critical comment on these assertions one must remark that the whole question of calcium metabolism is in great confusion. The methods of quantitative analysis at present in use are only approximative. It is generally supposed that the quantity of calcium in the blood is normally only ten or twelve mg. to the hundred c. c. of blood. When, as is usually the case, only minute amounts of blood (one or two c. c.) are used in the analyses made, the experimental error is enormously multiplied in the final result. Before the hardheaded clinical practitioner draws any conclusions on the subject, he will ask for many more facts and many more confirmations of supposed facts than are now available. The calcium content in a great many diseases has never been studied at all, so far as I know; and in diabetic acidosis, in cancer, suppurative conditions and uremia, researches so far made seem to indicate that a marked lowering of the calcium content of the blood is unassociated with any signs of tetany whatever.

The same objections must be raised in the matter of guanidine poisoning. The subject requires far more research, and far more unanimity of conclusion than has been so far attained.

The parathyroid question is further complicated by a large number of latter day studies on tetany in its relation to alkalosis of the blood. The literature is pretty fully given in the recent paper by I. Greenwald (22). The various observations so far published are interesting, but as usual the conclusions arrived at are in many instances but ill justified by the protocols.

PARATHYROID THERAPEUTICS

The present status of the chemical theory is confusing, and offers but little satisfactory help in the identification of possible parathyroid diseases. The clinical signs of postoperative tetany are of more value, and it is upon these that we must still mostly rely.

Nothing is so far clinically known of hyperparathyroidism. Nothing is known of dysparathyroidism. Of hypoparathyroidism, however, there is one certain condition in man, tetany following total thyroidectomy, and two conjectural conditions, idiopathic tetany, and certain types of paralysis agitans.

The convulsive symptoms of parathyroid tetany have led various authors to suppose that epilepsy, eclampsia gravidarum, and eclampsia neonatorum are parathyroid conditions. MacCallum and Vassale tentatively suggested epilepsy twenty years ago. The notion died out entirely, so far as I know, till A. Bisgaard (23) and Bisgaard and Hendricksen (24) revived it. They based their conclusions upon the rather slender claim that the dysregulation of the H ion concentration of the blood in postoperative tetany is also to be observed in epilepsy.

The supposed relation of the parathyroids to calcium metabolism led Vines (*loc. cit.*) to examine the calcium of the blood of a number of patients with various suppurative diseases. He found the calcium reduced in patients with varicose and other ulcers, and claimed that parathyroid was curative. H. H. Scott (25) found the ionic calcium of the blood diminished in the dangerous and obstinate disease, tropical sprue. Giving calcium caused improvement, and giving calcium and parathyroid caused rapid improvement, with apparent cure. In Manson's *Tropi-*

cal Diseases (7th ed.) is to be found the curious note in this connection that an irregular practitioner in Shanghai in former years got up quite a reputation for the treatment of this disease with a secret remedy. The drug was supposed to be some form of lime, probably powdered cuttlefish bone.

Getting still further away from any clinical or laboratory indications, various medical writers have reported parathyroid as curative of arthritis deformans, Graves's disease, paroxysmal tachycardia, and a curious list of other rather miscellaneous conditions. Of these one must remark that the cases have been imperfectly reported, that no note was made of other remedies used, and that the number of socalled cured cases was far too small to exclude the coincident beneficent working of the *vis medicatrix naturæ*.

Returning therefore to firmer ground, I will comment at more length on the first three diseases mentioned.

POSTOPERATIVE TETANY

Surgical tetany is a condition sometimes following both partial and total surgical excision of the thyroid gland. It may result from, a, accidental removal of the parathyroids; b, operative damage of their blood supply; c, postoperative suppuration; d, late cicatricial strangulation. This accident is still occurring every now and then in the best regulated hospitals. In Germany it is admitted to be on the increase, and is attributed (M. and K. Grasmann) to the current tendency to ligation of too many of the nutrient vessels. In America it is hard to get any details; surgeons do not publish them! The condition is, however, always one to be borne in mind, for the results run all the way from mild evanescent tetany disappearing for good and all in a few days, to a dreadful acute tetanoid state, or even tetanic convulsions, followed by speedy death.

Treatment.—Prevention is the rational treatment. If the rules for operation laid down very plainly in the modern textbooks of surgery are carefully followed by the surgeon, the accident will never occur. When the symptoms have unmistakably developed, the treatment consists of intravenous calcium injections from time to time, and the administration at proper intervals of oral and subcutaneous doses of a standardized preparation of parathyroid. The principle is that these remedies may possibly keep the patient alive long enough for the development of accessory tissue.

Grafting a gland is a forlorn hope, so rarely satisfactory that one may well doubt whether in the few successes that have been reported the diagnosis was correct.

IDIOPATHIC TETANY

This is a disease about which much has been written, and little is actually known. Many experienced practitioners in American cities have never seen an adult case, though it is more common at all ages on the continent of Europe. In making the diagnosis the "obstetric hand" (Trousseau's sign) is mainly relied on both in adults and children; but this sign often appears temporarily in a miscellaneous multitude of evidently unrelated diseases, and is a poor dependence. I once saw it as a persistent hysterical symptom in a young woman otherwise in superb health.

Many writers try to differentiate infantile tetany and "spasmophilia" (whatever that may be) from the ordinary idiopathic tetany of adults. The blood in many of the infantile cases has been found deficient in calcium, and on the continent the profession generally consider symptomatic tetany at any age as a hypoparathyroidism. The suggestion originated with Jeandelise, so far as I am informed, and dates from early in this century. One may accept it as a working hypothesis of the causation of a certain proportion of the cases.

TREATMENT

Treatment theoretically consists in giving calcium and parathyroid, and in the relief or removal of complications. Complications in babies are diarrhea, rickets, and malnutrition; and in adults, pregnancy, dilation of the stomach, and industrial poisonings of various kinds. Each of these conditions is to be cared for in the proper way, if the tetany is to be permanently abolished.

PARALYSIS AGITANS

The possible connection of this disease, or of some forms of it, with chronic deficiency of the parathyroid glands was suggested by Lundborg, of Stockholm, in 1904, and by the writer independently in 1905. As far ago as 1886 Victor Horsley hinted at it after observing the tremors in some of his thyroidectomized animals; but he knew nothing of the parathyroids, and supposed the thyroids to be at fault.

In another place (26) I have enumerated at length the considerations that lend some probability to the connection between the parathyroids and Parkinson's disease. The symptoms are strikingly similar; the disease has been sometimes associated with Graves's disease, and with myxedema, where one might not unreasonably surmise that the circulation of the parathyroids has been damaged by the adjacent thyroid trouble; and finally, in hundreds of cases of Parkinson's disease in the care of physicians all over the world, a majority of the patients have been benefited by parathyroid medication, when real parathyroid gland was given.

Many of the patients have been remarkably relieved. There is hope of some benefit in all patients except those afflicted with the agitans syndrome following severe cases of influenza (epidemic encephalitis?). Here, unfortunately, even the largest and most carefully administered doses are entirely without effect.

BEDSIDE DETAILS

Extracts of parathyroid.—Berkeley and Beebe (*loc. cit.*) found that acetic precipitates of alkaline parathyroid solutions were active in relieving canine tetany (fifteen minutes to an hour or so). This extract is killed by boiling, and slightly damaged by artificial digestion. J. B. Collip and coworkers (27) announce that they have produced a very active extract by boiling the minced glands in dilute hydrochloric acid, and that they can not only relieve canine tetany by injecting this extract, but can by repeated injections cause a hypercalcemia (fourteen mg. to the one hundred c. c. of serum) in dogs and that such dogs may even finally die. It does not, however, as yet appear that the dogs die from the hypercalcemia.

Dr. Collip's extract is called parathormone. Though there are as yet no announcements (that I

know of) identifying this extract as a definite chemical entity, its discovery evidently marks an important advance in our chemical knowledge. Dr. Collip seems at present to think that it belongs to the proteins.

The Berkeley-Beebe extract I am accustomed to give in doses of one fiftieth grain several times a day. It may be given by mouth, by hypodermic, or in both ways. It is now to be had of several New York wholesalers. To the hypodermic there is no local reaction.

CONTRAINDICATIONS

For this preparation there are virtually no contraindications. Among the hundreds of patients with paralysis agitans in the care of myself or of medical friends in the last few years I have never had but one patient who could not take it. Dr. Parcher, of Saugus, Mass., wrote me of a lady in his care who appeared to grow hysterical after two or three doses, and refused to go on with the treatment. One English writer has recently reported diarrhea in children after the use of a commercial extract (maker's name not stated). This does not sound alarming. It is possible, however, that Dr. Collip's preparation may prove much more potent, and that its administration may require more circumspection.

The ordinary commercial extracts made by American dealers are uncertain, and as far as my experience goes, mostly inert. The extract used in England by Dr. Vines was given in doses of one tenth grain.

In conclusion, one may observe that while parathyroid may occasionally save a life in surgical tetany, it is of secondary consequence in idiopathic tetany, and that its great service so far at the bedside has been in the relief of the symptoms of paralysis agitans. Whether its action in this disease be specific substitutive gland therapy, or only a symptomatic influence, the clinical facts remain the same.

A physiologically tested preparation must be used.

210 East Sixtieth Street.

Insulin Practically Applied in the Treatment of Diabetes Mellitus

WILLIAM GOLDRING, M.D.
New York

In the past year and a half we have treated ninety cases of diabetes mellitus in the Third Medical Division of Bellevue Hospital. Our mortality was ten cases or eleven per cent. Four of these patients died of bronchopneumonia, two of hemorrhage into the cerebrum, one of acute miliary tuberculosis, one of postoperative shock, one of diabetic coma, and one of hypoglycemic shock. The case of diabetic coma was complicated by a lung abscess and high temperature. The patient had been given 250 units of insulin in a period of thirty-six hours with no result; the blood sugar before treatment was 420 mgms. per one hundred c. c. of blood and fifteen minutes before death was still 400 mgms. The deaths from diabetic coma were therefore about one per cent.

In order to treat rationally a patient with diabetes mellitus one must be familiar with the underlying metabolic changes. In normal metabolism a relation exists between the fatty acids (ketogenic substance) and carbohydrate (antiketogenic substance), so that two to three gms. of the former are burned always in conjunction with at least one gm. of the latter. Failure of the body to utilize this proportional amount of carbohydrate while continuing to burn fat in normal or more than normal amount, results in incomplete combustion of fat, with the production of the socalled acetone bodies. The appearance of these substances in the urine (acetone, diacetic acid, and beta oxybutyric acid) is Nature's signal of an impending intoxication and treatment therefore must be immediately directed toward the prevention of their formation, before their accumulation has lowered the alkali reserve of the blood to a dangerous degree.

The second consideration in the treatment is to render the urine sugar free and reduce the blood sugar to normal.

The third, is to increase the patient's tolerance so that his urine is sugar free and his blood sugar normal, on a diet sufficient in caloric value and with a proper proportion of fat protein and carbohydrate to carry on normal metabolism.

The cases of diabetes which we have been called upon to treat have ranged from mild ketosis up to impending coma and actual coma. In the mild cases, treatment need not be directed toward the acidosis, for it will be found during the process of eliminating sugar from the urine and reducing the blood sugar to normal that the slight evidence of intoxication present will disappear within three or four days.

In the cases of impending coma, however, treatment must be prompt and drastic and directed solely toward the acidosis without any regard to the degree of hyperglycemia or the amount of sugar excreted. Such cases are characterized by drowsiness, dry, red, fissured tongue, acetone odor to the breath, flushed cheeks, air hunger, subnormal temperature, mental confusion or delirium.

First, the temperature is brought up to normal and maintained there by external heat and a high, hot colonic irrigation. Then a hypodermoclysis of one thousand c. c. of normal saline is given, in one dose or divided doses depending upon the condition of the heart and circulation. The patient is now in a suitable state for the beginning of intensive insulin treatment.

During active treatment with large doses of insulin, urine examinations are of much greater value than blood examinations, and this for three reasons: first, the blood sugar estimations vary with the concentration of the blood and in the early stages of the treatment when the patient is dehydrated, are not to be relied upon, while the clinical aspect of the patient is a sure indication of a lowered alkali reserve in the

blood: second, the disappearance of acetone from the urine is good evidence that the patient is out of immediate danger; it is then that the blood sugar and carbon dioxide estimations do become important factors in the regulation of the diet and the dosage of insulin to be prescribed thereafter: third, blood sugar and carbon dioxide estimations entail invariably some loss of valuable time when immediate treatment is urgent. In the hospital, nevertheless, we do make a blood examination on admission, merely for record and future reference, but insulin treatment is begun without waiting for the report.

INITIAL DOSE OF INSULIN

Having now increased the patient's resistance by raising and maintaining the body temperature at normal and giving fluid by hypodermoclysis, a urine specimen, drawn by catheter (making sure to empty the bladder completely) is examined for acetone and quantitatively for sugar. Then forty units of insulin are given intravenously with forty gms. of glucose in a ten per cent. solution by mouth. The carbohydrate is given as a safety procedure. The purpose of this first dose of insulin and carbohydrate is to create a large carbohydrate flame in which to burn the fat metabolized at that time and so prevent the further formation of ketone bodies.

The insulin will continue to have its effect for four to six hours. During this period the patient is watched for signs of increasing toxemia, for which heat, sodium bicarbonate and hot retention enemata are valuable; and for failing circulation for which digitalis and caffein are used. We have found that gamma strophanthin given intravenously is a rapid and effective circulatory stimulant. The dose is .005 mgm. per pound body weight given in two doses one hour apart.

At the end of this period of four hours the patient is again catheterized, making sure again that the bladder is completely emptied, and the urine obtained is examined for acetone and quantitatively for sugar.

Owing to the uncertainty of the exact amount of insulin required when treatment is begun we selected forty units for our initial dose rather than a larger amount. While this dose produced in most cases no change either in the urinary acetone or sugar, there was clinical improvement, and we felt it was adequate as an initial dose. Four hours after the initial dose forty units more of insulin were given, this time subcutaneously and forty gms. of glucose by mouth. For comatose patients the second dose of insulin was given intravenously. Noncooperating patients and patients in coma were given glucose by Murphy drip, five per cent. retention enema, using six ounces of water, or by stomach tube. Alkalies were not used.

After this second period of four hours the urine was again examined. In our series the acetone was invariably found to be greatly diminished, the sugar remaining about the same. The patient at this time having had eighty units of insulin in a period of eight hours begins to show signs of marked improvement. This is best seen in the diminution of air hunger and restlessness and the return of coherence.

Since there is no need to burn an amount of carbohydrate above that required for the complete oxidation of the fat metabolized, we found that ten units of insulin and ten grms. of glucose given every four hours were sufficient for a person weighing about sixty kilos (average weight). Our subsequent dosage of insulin varied somewhat with the patient's weight, but ten units every four hours were usually sufficient. This was continued for three to five doses when in practically all instances the urine became acetone free. If blood examinations are made during this period it will be found that the sugar remains about the same but that there is a steady increase in the alkaline reserve.

This procedure required, as a rule, about ninety to one hundred and fifty units of insulin and extended over a period of twelve to thirty-six hours.

SECOND STAGE OF TREATMENT

The patient is now out of immediate danger from coma and the second process in the treatment is begun, namely, the reduction of the blood sugar to normal and making the urine sugar free.

The patient is now put on a basal diet roughly computed as one gram of carbohydrate per kilo body weight, one gram of protein per kilo and two and one half grams of fat per kilo. Now enough insulin is given to metabolize the amount of carbohydrate in the diet plus the amount of carbohydrate excreted in the previous twenty-four hours. The latter figure must be determined before the patient has been put on a basal diet.

In deciding upon the amount of insulin to be used at this stage of the treatment, it is to be kept in mind that while in a case of coma one unit will metabolize approximately one half a gram of carbohydrate, in a moderately severe case it will metabolize one to two grams, and in the milder, three to five grams.

BASAL DIET

The patient is now on a basal diet eating equal amounts three times a day and receiving one third of the total daily dose of insulin twenty minutes before each meal. If the patient cannot chew solid food a suitable diet can be arranged with milk, cream and eggs. One quart of milk, one pint of cream (twenty per cent. fat) and two eggs contain fat 148 grams, protein sixty-eight grams, and carbohydrate fifty-six grams, making a total of 1828 calories. This is a basal diet for a person weighing about sixty kilos. Under such conditions the urine usually becomes sugar free in, from three to five days; if it does not, the insulin is increased, the increase in insulin depending upon the amount of sugar excreted in twenty-four hours, allowing one unit for every three grams.

When the urine has become sugar free on a basal diet and the required amount of insulin (our average case required about thirty units a day) the diet is slowly and proportionately increased until the patient is receiving sufficient calories to carry on his customary activity. During this process the dose of insulin in some instances had to be slightly raised.

While increasing the diet it is important to keep a proper relation between the fatty acid and the carbohydrate so that the ratio is never more than three grams of fat to one gram of carbohydrate preferably two and a half to one, because too great a preponderance of fatty acid over the carbohydrate tends to produce ketosis, the first evidence of which is the appearance of acetone in the urine.

The patient continues on this adequate diet plus insulin for about ten days. Since we have found that insulin undoubtedly increases carbohydrate tolerance it can be reduced gradually, five to ten units every three days, or until sugar again appears in the urine. If the sugar persists for three days the insulin is increased again to an amount just sufficient to take care of the sugar excreted. After three days the insulin is again gradually cut down. This process is continued in this manner in three day periods until the patient stays sugar free on an adequate diet without insulin. In our series only three patients were discharged from the hospital still requiring insulin, and this because they refused to stay until the insulin could be safely discontinued.

There are cases in which the patient is apparently out of danger, the blood sugar normal and the urine sugar free, yet there is an abundance of acetone, or both acetone and diacetic acid in the urine. This can be promptly corrected in every instance by adding more carbohydrate to the diet or reducing the fat, so as to establish the proper ketogenic antiketogenic ratio.

Another type of case we have frequently seen is one which, with a perfectly normal urine, the blood sugar remains persistently high (350-500 mgrms. per one hundred c. c. blood). These cases will respond very promptly to dietetic treatment alone. Such patients should be started on a diet of fat ninety grams, protein twenty grams, carbohydrate ten grams, which should be increased proportionately about one hundred calories every three days until a maintenance diet is reached.

While using insulin the danger of causing hypoglycemia should constantly be borne in mind. This can be avoided early in the treatment by always giving at least one gram of carbohydrate for every unit of insulin, and later in the treatment by reducing the insulin or increasing the diet as soon as the urine becomes sugar free.

Febrile patients require more insulin than afebrile patients, so that when the temperature becomes normal or definitely lowered the insulin should be stopped or reduced to about half the original dose.

When a patient has received a dose of insulin and does not eat or vomits the allotted meal, one gram of carbohydrate for each unit should be given immediately without waiting for symptoms, because the effects of hypoglycemia may come on with great suddenness and even produce coma within a few minutes.

If the above rules are carried out carefully the danger of hypoglycemia is very slight, except perhaps in cases of idiosyncrasy to insulin, but we have seen no instances of this.

To recognize hypoglycemia one has only to bear in mind the symptoms of diabetic acidosis, for in hypoglycemia the patient presents a train of symptoms which are almost just the reverse. The skin is pale and moist, there is marked perspiration about the forehead and chest, the respirations are rapid and shallow, there are tremors and twitchings of the extremities, delirium and finally coma. The most characteristic signs are pallor and sweating which are never seen in the hyperglycemic state.

A patient we treated recently was admitted in impending coma. She ran a temperature of 99° to 102° F. due to a severe cellulitis of the leg. After four days she was out of danger from diabetic coma, her blood sugar stayed at 170 mgms. per one hundred c. c. and her urine was negative for sugar and acetone on sixty units of insulin a day and an adequate diet. On this same diet the sixty units of insulin were continued for seven days after the temperature had become normal when although apparently doing well she suddenly became comatose in a few minutes. Her blood taken immediately showed twenty mgms. of sugar per one hundred c. c. and she presented the typical signs of hypoglycemia. Treatment was started within fifteen minutes after the onset. Two hours later the blood sugar was 270 mgms. but the patient remained comatose and died within forty-eight hours. No autopsy was granted. It was assumed then that perhaps the hypoglycemia causes some organic cerebral lesion which accounts for the persistence of coma even after the moderate hyperglycemia has been reestablished, just as one sees following carbon monoxide poisoning after the carbon monoxide has been removed from the blood.

Another case which had not progressed to coma was relieved in a few hours by fifteen minims of adrenalin (one to one thousand) by hypodermic injection and the juice of one orange by mouth.

INSULIN AN AID IN TREATMENT

It will therefore be seen from our series that insulin is merely an aid in the relief of diabetic acidosis and that it is not necessary and may even be harmful in the mildly toxic cases that will respond to dietetic treatment alone. It will also be seen that the dose of insulin, in the great majority of cases, is more or less constant and should never be given haphazardly. The dose should be controlled by a constant diet, a daily urine examination, and occasional blood sugar and carbon dioxide estimations. Since the advent of insulin it is no longer necessary to starve a diabetic patient for the first few days and in the milder cases the patients may be placed on a basal diet when first seen, using insulin only if sugar persists in the urine for three days.

Acetone in the urine in the absence of sugar always indicates a deficiency in carbohydrate or an excess of fat in the diet, and can easily be corrected. Sugar in the urine in the absence of acetone indicates an amount of carbohydrate in the diet above the patient's tolerance and can be corrected by giving a small dose of insulin or reducing the daily intake of food. Hyperglycemia with a normal carbon dioxide and a negative urine can be corrected by a dietetic treatment alone. The use of insulin in these cases is dangerous and moreover the dose is very difficult to control.

CONCLUSIONS

1. Blood examinations are not essential during the administration of large doses of insulin early in the treatment of severe cases; the urine is a more practical guide.

2. In severe cases the initial dose of insulin need never exceed forty units intravenously, and one gram of carbohydrate should be given for each unit.

3. Alkalis are not necessary for the relief of diabetic acidosis, when insulin is used.

4. Insulin increases carbohydrate tolerance.

5. Hypoglycemia is not a common occurrence.

Third Medical Division, Bellevue Hospital.

Practical Therapeutics

TINCTURE OF IODINE IN ROUTINE PEDIATRIC PRACTICE

HERMAN B. SHEFFIELD, M.D.
New York

Of all the drugs in the pharmacopœia none has so broad a field of usefulness in the hands of the general practitioner as the preparation under discussion. Long before the surgeon had accepted it as an ideal local antiseptic in operative procedures, tincture of iodine had served the physician as a sovereign remedy in all sorts of local infections, bruises, sprains, pains of indefinite etiology affecting the bones or muscles, and in various enlargements of the lymphatic glands.

RINGWORM

It has proved to me an ideal parasiticide in diverse skin diseases. About thirty years ago on being appointed attending physician to the Hebrew Sheltering Orphan Asylum, which at the time accommodated over eleven hundred children, I was rudely confronted by a most virulent epidemic of tinea tonsurans affecting over four hundred children. Ringworm of the scalp in sporadic form is quite common in children's institutions, but in this case the careless use of hair clippers was probably responsible for the rapid dissemination of the disease. In the last three months the epidemic had become so serious in character that the services of the late celebrated dermatologist, Dr. Lustgarten, were solicited to stay its ravages. Do what he would, the epidemic stubbornly persisted and, as a last resort, he resorted to the free use of chrysarobin in tar oil, but without appreciable results. Not only had this treatment failed to effect a cure, but it proved very costly—thousands of pillow cases and sheets having been stained and burnt beyond repair. It was very painful to the children and laborious to the nurses, requiring as it did careful epilation of the loose hair.

Having previously cured tinea circinate by means of tincture of iodine, this remedy naturally suggested itself to me also on this occasion. But I soon learned that the too frequent application of iodine was productive of intense inflammatory reaction, and hence sought the best means of getting the benefit of the iodine without its detrimental effects. After considerable experimentation the following mixture proved to meet all indications:

Tinct. Iodini
Olei Ricini a a ʒiiiss
Acidi Phenolis
Olei Petrolei crudi a a ʒii
Olei Rusci q. s. ad ʒxvi

After clipping the hair close to the scalp the mixture was applied (by means of a small painter's brush) over the entire scalp, more thickly on the affected spots, once a day for five successive days. On the sixth day, the mixture was wiped off by means of waste cotton dipped in linseed or olive oil; the hair was clipped again and the scalp thoroughly but gently washed with the tincture of green soap. No epilation of the hair was required. The whole process was repeated for three or four successive weeks—when it was usually found that the trichophyton fungus had disappeared and that new hair was appearing upon the bald spots. By applying the mixture over the entire scalp we were enabled, not alone to arrest the transmission of the disease from one child to the other, but promptly to arrest the newly developed infections at their inception and also to prevent autoinoculation from one part of the scalp to another. This course of treatment was advantageously followed by a few applications of sulphur ointment or a two per cent. solution of resorcin and salicylic acid in alcohol and castor oil. In order to avoid staining of the bedding the child had to wear an oiled silk skull cap at night. It may be of interest to note that this method of treatment of tinea tonsurans has since become the treatment of choice in several large children's institutions throughout the country.

As already stated ringworm of the body yields promptly to a few applications of the undiluted tincture of iodine. In ringworm of the nails, on the other hand, the iodine has to be applied daily for several weeks, preferably enveloping the fingers in cotton and narrow bandages. In very stubborn cases the aforementioned mixture has invariably cured the cases under my observation.

PARONYCHIA

Paronychia can frequently be arrested in its inception by the use of iodine. A few drops of the tincture is instilled in the nail bed and well surrounded by a pledget of absorbent cotton and several strips of adhesive plaster. Usually only one dressing is required. This mode of treatment is particularly useful in paronychia affecting diabetics, in whom surgical procedures are generally contraindicated.

ADENITIS

In diverse forms of adenitis and local effusions tincture of iodine promptly and properly applied often arrests suppuration and hastens absorption of fluid. It should be remembered, however, that in order to obtain good results the affected parts must be well covered with cotton and bandages, completely to exclude the air, since, otherwise, the iodine is quickly evaporated.

ENLARGED JOINTS

Numerous cases of enormously enlarged joints, due to bursitis, synovitis, or arthritis sometimes resembling those of a tuberculous nature have promptly responded to a few applications of iodine externally. And sceptical as one is bound to be about the systemic action of iodine when applied locally, I nevertheless feel fully justified in recording that in many instances pleuritic effusions have entirely been absorbed by the means of the following mixture, applied externally for from three to ten days:

Tinct. Iodini
Guajacolis
Olei. Gaultheriæ a a ʒii
Liq. Petrolati q. s. ad ʒiv

Very recently I had an opportunity to corroborate my opinion of the specific action of tincture of iodine

in arresting the spread of erysipelas. The little patient was two weeks old and contracted erysipelas after circumcision. As the condition of the child was becoming very serious, the family physician consulted a prominent pediatrist, who predicted all sorts of grave possibilities. When I saw the baby the next day, the inflammation had already involved the entire lower extremities and had spread above the umbilical region. I painted around the baby's body, above the line of demarcation, two circles of iodine one inch wide and two inches apart, and advised advancement of the circles as the redness passed the borderline. The following day I was gratified to learn that the erysipelas was promptly arrested in its advance. I was consulted, however, again a few weeks later regarding the appearance of several abscesses on the baby's body which required incision and drainage. In this connection it may be of interest to relate that one of the abscesses had become localized at the lower lumbar region and was diagnosed by a surgeon as a spina bifida—rather a pompous diagnosis, considering the clarity of the history of the case.

NOSE AND THROAT AFFECTIONS

The value of iodine in nose or throat affections has long been recognized by the profession at large. With the exploitation of the numerous newer silver preparations, however, its use has recently become somewhat restricted; yet it still has many adherents. A one per cent. solution of tincture of iodine, in glycerine, preferably combined with a one quarter of one per cent. of carbolic acid, often acts very efficiently in chronic rhinitis and rhinopharyngitis, and in suppurating adenoids. As in these cases the submaxillary glands are generally implicated as well, it is of advantage to apply also a five per cent. solution of tincture of iodine in liquid vaseline to the swollen glands. Tincture of iodine acts almost as a specific in cases of postoperative infections after adenotonsillectomy, manifesting itself by persistent hyperpyrexia, undue sloughing of the tissues, and symptoms of general sepsis. Often after one swabbing of the throat all the symptoms disappear as if by magic. The application may be repeated once or twice a day for several days if necessary. It may also be mentioned here that the spasmodic coughing and extreme difficulty in swallowing, which occasionally result from injury or infection of the uvula during the tonsillectomy, are also quickly remedied by a few applications of tincture of iodine. In tonsillitis and cognate affections I prefer the following mixture:

Tinct. Iodini
Tinct. Myrrhae a a ℥i

Sig: Ten drops in a wineglassful of water to be used either as a spray or gargle every hour or two.

The same formula acts very beneficially also in stomatitis, pyorrhea, and gingivitis, while in alveolar abscess the undiluted tincture of iodine applied *pro re nata* is to be preferred.

As regards the use of tincture of iodine in pyorrhea alveolaris, I believe it is to be regretted that the modern dentist is gradually discarding so useful a remedy and is instead exploiting the numerous new, often worthless, products which are being foisted upon the credulous public by shrewd pharmaceutical mercenaries.

COLLOIDAL THERAPY IN MALIGNANCY

(A Preliminary Report)

Donald C. A. Butts

Philadelphia

Since the recognition of colloids (the colloidal state of matter) as separate and distinct from crystalloids (Graham, 1861), the theoretical, experimental and clinical studies of colloidal chemistry have gained much ground and recognition. In so doing, many new phases of physics, biology, chemistry, and therapeutics have been opened up and developed to an astonishing degree.

In this entirely separate field of chemistry, speculation has given way to determined facts and deductions, this statement holds good regarding the contents of the brief report herewith submitted.

In June, 1923, I read, and later published (1) a report incorporating several theoretical and experimental phases of the use of colloids in the treatment of malignancy. At this time I suggested the use of the anionic colloids (negatively charged, passing to the positive pole) to adjust the physicochemical alterations which I had found existing in neoplastic tissue. Since that time, due to extended biological experimentation, combined with an extensive investigation in the fields of radiology and röntgenology, my former suggestions are apparently now firmly established, and I feel that a second clinical report is justified at this time.

Before issuing the report referred to, it was determined by accurate experimentation with standard laboratory strains of rat tumors that such tissue (neoplastic tissue) existed in an electropositive state of physical or physicochemical unbalance as compared to normal tissue; or in other words, such tissue was possessed with a greater or higher potential than was normal tissue.

Such determinations were made by means of a highly sensitive galvanometer. After the completion of this test the animals were treated with electronegative colloids, which reversed the current flowing through the galvanometer, showing that tissues, formerly with a greater or higher potential, were rendered neutral insofar as physicochemical metabolism was concerned. These animals likewise showed marked improvement, both local and systemic, following such treatment.

Extensive experimentation in the fields of radiology and röntgenology demonstrate that the negative electrons, manifested as beta rays of radium or corpuscular radiations from the röntgen tube, possess like effects, and these rays alone are responsible for the desired biological cell change.

Those who are employing radium as a means of therapy in malignancy are naturally confronted with its limitations with which to combat dissemination. The limitations of röntgen therapy are, however, not so great, but will require a long period of research to determine the best means of handling, to cope scientifically with such problems.

To span the time until such developments can be brought about with röntgen therapy, or for use in preventing and combating metastases, I have advocated the use of electronegative colloids in the treat-

ment of inoperable cases, or in any case where widespread dissemination is likely.

If cells comprising malignant neoplasms exist in an electropositive state, and metastases occur by cells migrating from their initial pathology to another part of the body, it is quite reasonable to suppose that such cells are endowed with, and convey the physical properties, i. e., electropositive state, as possessed by the primary growth.

Upon this reasoning, we believe that these cells may be returned to a condition of normality by the use of electronegative colloids, and in such manner prevent the formation of secondary deposits; or if such deposits do exist, they may, in a similar way, be rendered potentially inactive and harmless.

From such theoretical and experimental deductions, the electronegative colloids of sulphur, iodine, and selenium have been put to extensive clinical use with extremely gratifying results.

Unfortunately the majority, if not all cases, treated by this means of therapy have been prognosticated hopeless. Many were postoperative, and irradiated, and the great majority were of recurrent type.

Coming under this method of treatment were cases of advanced carcinoma of the liver, uterus, lip, stomach, and various forms of superficial lesions of carcinomatous type. Many of these were verified malignant by pathological section. The cases not subjected to biopsy were pronounced malignant by competent authorities.

The majority of the patients have been materially benefited, some going on to apparent recovery. In all cases pain was almost immediately relieved (narcotic administration could usually be discontinued or greatly reduced), gastric and constitutional conditions benefited.

From the observations noted above we feel that this method of therapy is of great advantage for relieving pain, prolonging life, and giving the patient a possible chance for recovery.

Intravenous Use of Acriflavine in Gonorrhea. H. Jausion, E. Diot and N. Vourexakis (*Bulletin de l'Académie de médecine,* June 2, 1925) claim priority in the use of intravenous acriflavine injections in gonorrhea. Their main object is to overcome the more chronic cases by sterilization of all the periurethral glands, which do not respond well to local treatment.

Solutions of 1:200, 1:100 and 1:50 of acriflavine in distilled water are used, the best practice, according to experience with 1,417 intravenous injections, being to inject five mils of the 1:50 solution at a dose, thrice weekly. In hospital cases, however, daily injections of five mils of the 1:100 solution or of two or three mils of the 1:200 solution are favored as yielding a more sustained effect. In administering the injection, the patient's blood is mixed with the dye solution in a ten or twenty mil syringe by drawing the piston back and forth and the whole then slowly injected. The injections are continued until recovery is obtained, this requiring generally ten to fifteen injections in incipient gonorrhea, twenty in an ordinary established gonorrhea, and about thirty in gonorrhea of several years' standing. Intraurethral injections are superfluous. Indiscretions of diet or drink interfere but little with the results from the intravenous treatment. Out of sixty-seven cases receiving this treatment, thirty-seven were completely cured, with cessation of discharge and disappearance of gonococci; fifteen showed good results, promising an ultimate cure; eleven were less markedly improved, and four were actual failures. Many of the cases had previously had numerous recurrences or reinfections. In initial, incipient injections, three or four injections generally abort the disease, and the gonococci disappear in twenty-four to forty-eight hours. In the older cases the discharge may stop abruptly or only after the gonococci have been absent for some time. A case of posterior urethritis with cystitis, prostatitis and cowperitis, followed by epididymoorchitis and iritis, was cured in forty days of exclusively intravenous treatment. Reactions from the injections are very slight and evanescent, and no alarming reaction occurred in 1,417 injections. Eventually a slight pseudoicterus, as a rule hardly noticeable, may develop.

In treating women the method is particularly serviceable, on account of the widespread gonococcicidal action which is required.

Treatment of Carbuncles.—Walter Estell Lee and T. McKean Downs (*Therapeutic Gazette,* October 15, 1925) state that carbuncles differ from other forms of suppuration in the subcutaneous tissues because of the anatomical and mechanical factors present in the region in which they occur, namely, a thick tough true skin connected with the underlying fascia by strong vertical fibrous septa. These factors not only prevent the breaking of the original focus through the skin, but also force it to spread laterally and become pocketed in the honeycomb like area.

The tension is perfectly relieved in all these pockets of infection, when, in addition to the usual crucial incisions, incisions are made in each section parallel to the skin surface, which opens all the diseased fat columns. When this has been done, each area of infection acts like a separate boil, and is able to drain freely onto the surface. The simple crucial incision is not efficient; excision *in toto* is unnecessarily destructive and prolongs the time of disability. Certain other treatments for carbuncles which have been advocated are discussed and reasons given for their condemnation.

Intracardiac Adrenalin Injection in Grave Collapse Under Spinal Anesthesia.—Cotte and Cartotto (*Presse médicale,* May 30, 1925) report a case of severe collapse toward the end of an abdominal operation under spinal anesthesia. In spite of artificial respiration and injections of caffeine and ether, the breathing and heart contractions had ceased, the pupils were dilated, and the corneal reflex was lost. A few seconds after intracardiac injection of two milligrams of adrenalin, the patient came out of his collapsed state, and he was later restored to health.

Historical Medicine

Portraits of Charcot

DR. HENRY MEIGE

Professor of Anatomy at the School of Fine Arts, Paris

(Translated from *Aesculape*, May, 1925)

INTRODUCTORY NOTE

This year is the centenary of Charcot's birth. One of the men who knew him best, not only in the fame of his clinical teaching, but also in the intimacy of his home life, was Dr. Henry Meige, professor at the School of Fine Arts, and he has made a study of the various portraits of his great master. We are very grateful to him for this. Our gratitude is due also to Dr. Jean Charcot, through whose courtesy we have been permitted to use the illustrations which supplement this article.

Both the body and the mind of Charcot were exceptionally impressive. Dr. Henry Meige, in a study of Charcot the artist, published in 1898 in the *Nouvelle Iconographie de la Saltpêtrière,* has given us his essential characteristics: "Charcot was grave; his mind, trained from his early days for studious thought, remained perpetually absorbed in the research of the new problem. He talked little; scientific discipline had taught him to weigh the precise value of words. His approach was cold, his greeting imperceptible, his hand advanced only half way, and there was rarely any response in its clasp; he had no use for the manifestations of merely banal politeness. Moreover, Charcot, even at the summit of his glory, retained always a vestige of timidity.

"As to his face, somewhat like a theatrical mask, firmly adapted to the rôle of miraculous warrior, is is not superfluous to recall that nature alone created it to express all these characteristics? This mask was at twenty the same as at sixty, with black hair more or less rumpled, but always dressed in the old fashioned manner, impassive, a bit enigmatic, impressive. The daily use of the razor which emphasized his Cæsarean profile, was the only artificial addition made to nature's work. . . ."

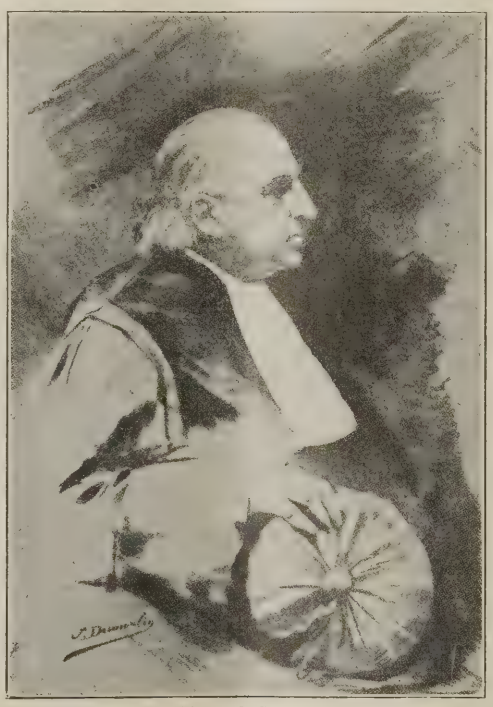

FIG. 1.—An etching of Charcot by Demoulins.

We celebrate, this year, the centenary of one of the glorious personalities of French medical history —Charcot.

This work will be commemorated on this occasion by those of his pupils who especially enjoyed the privileges and benefits of it—Pierre Marie and Babinski. Another, Souques, enjoyed his intimate friendship. This article will be devoted only to the works of art which have helped to perpetuate the memory of the great personality of Charcot.

Very few great men have provoked representations of themselves. Scultures, paintings, medals, engravings, made from the living Charcot or after his death, constitute a document that should be examined.

Why this abundance of portraits? Had Charcot a weakness in thus humoring himself? Not at all. He attached no more importance to his appearance than to that of others; only spiritual qualities counted in his eyes.

If these representations are numerous, it is for two reasons: Charcot loved the fine arts; he had himself a very keen artistic sense and was himself a facile draughtsman. Consequently, he enjoyed the company of artists and took pleasure in encouraging their work. But, above all, no one was better endowed than Charcot for tempting the chisel, the brush or engraver's steel.

His face was unforgettable. A brow pure and powerful; entirely uncovered, hair combed back and falling down to the neck behind; a short nose, firm and straight; lips thin and a bit haughty; chin firm but not hard set; and above all deep eye sockets, like the ancients', within which one could see, shaded by heavy lashes, eyes sometimes very soft, sometimes imperious. Such a face could not fail to attract artists, and so one understands why there are so many portraits of Charcot.

During the first years of his scientific life the beauty of his profile, the mystery of his expression in which severity was tempered by a trace of timidity, attracted attention. Charcot was compared when young to Bonaparte, which did not flatter him, and moreover his head was large and long; he usually held it well forward, above shrugged shoulders. He was also said to have Dante's nose, and this was true enough. There was mention, too, of his Cæsarean profile, and it is true that upon seeing him one thought spontaneously of the beautiful bronzes of Roman art.

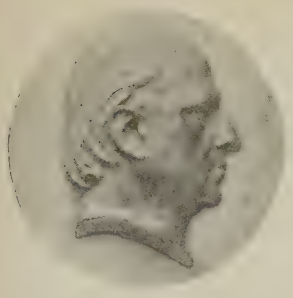

Fig. 2.—Medallion by Madame Charcot.

But Charcot was above all just Charcot; a personality unique not only in physique but in spirit.

It is in sculpture that portraits of Charcot are most numerous. The oldest bust of him was made about 1873 by an Italian sculptor established in Paris, Mezzara, friend of the painter Protais, the author of the *Dernières Cartouches*, himself a great friend of Charcot and of the painter sculptor Gérome. We see here Charcot at his age of greatest beauty, when he was graceful and slender with youth, and before his features had undergone the inevitable blemishes of age. His hair, still abundant, had even then the familiar backward sweep; the profile is very pure; the eye deep and of the kind that sees ideas rather than men. There is in his expression a gravity that is imposing and a remarkable contemplative quality.

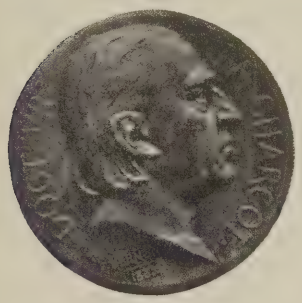

Fig. 3.—Medallion by Vernon. Collection of Prof. Pierre Marie.

Dalou has left a bust of Charcot which is a very beautiful work of art. One finds there the two dominating characteristics of this great artist; fidelity to nature, and the ability to fix expressions, no matter how fugitive they may be. This is why he has made of Charcot a portrait of the greatest truth and power. No flattery in the representation, perhaps too realistic, but in every detail of the work representing the most rigorous accuracy. However, Dalou was not satisfied with it; the ensemble did not express to his taste all he had seen, not all that he wished to bring out; a countenance and the thoughts back of it.

Another bust of Charcot was made by his own wife in 1880. Madame Charcot, born in a milieu where works of art abounded, had more than a taste for the beautiful; she had real artistic talent. She devoted herself, not only to her children, but also to beautifying her home; Charcot helped her. The bust that she made of her husband reveals some technical inexperience, but it is a good likeness and the expression is not without a certain nobility. It has in the eyes the alluring fire of old romance. Madame Charcot made also a medallion which depicts ably the unforgettable profile.

Fig. 5.—Bust by Dalou.

There is also a bust of Charcot by Dr. Vincent, whose artistic talent often had occasion to manifest itself at the Salpêtrière, when Professor Raymond occupied the chair in the clinic of diseases of the nervous system. Although this bust was made after Charcot's death, it is not without merit, and gives a good idea of the great master of French neurological science in the last years of his life.

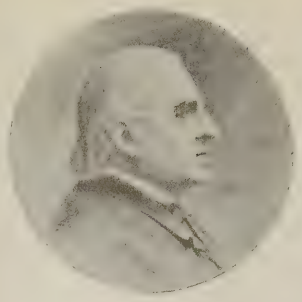

Fig. 4.—Etching by Professor Paul Richer (1891).

A statue of Charcot, standing, was unveiled some years after his death on December 4, 1898, through a subscription of his pupils and friends. Crowded up against the wall of the entrance pavilion of the Salpêtrière, this statue lacks space. The professional garb gives it heaviness rather than majesty. The head is powerful, but the features are hard. It well expresses the firm will which was one of the dominating characteristics of Charcot, but it lacks the light of his luminous mind and spirit. The extremities, too gross and too knotty, almost make us forget the fine elegance of the artist's hand. Was it necessary, in order to symbolize his studies of the brain, to place at his side this grotesquely deformed cadaver? A statue less pompous, serious and grave, standing on the ground in front of the Salpêtrière, counterpart to the statue of Pinel, would have left of Charcot a memory more sincere and more dignified. One feels that he himself would have wished this. Nevertheless the statue has its good points. One can see the mark of the great artist, Falguière. But one cannot help but regret that the latter, who nevertheless knew Charcot well—he was his fellow student at the *Lycée Bonaparte*—has given so much importance to costume, especially when Charcot during his whole lifetime showed himself to be scornful of apparel and indifferent to honorary insignia. Not only in his early youth, when he was acquainted with poverty, but also at the summit of his glory when riches overwhelmed him, Charcot loved only the simple. Moreover, he was always indifferent to questions of money.

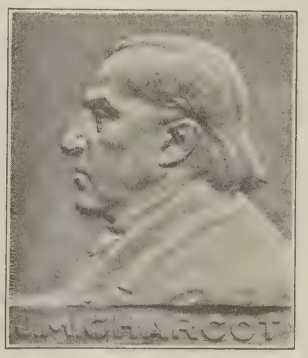

Fig. 7.—Medallion by Morlon (Salon of 1925).

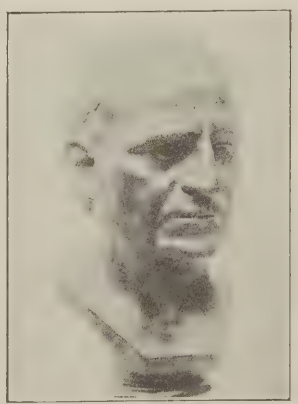

Fig. 6.—Bust by Madame Charcot.

There are also medals of Charcot. About 1883, having been appointed professor of the clinic of diseases of the nervous system at the Salpêtrière, he relinquished the presidency of the *Société*

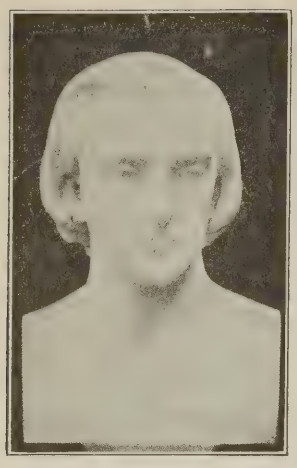

Fig. 8.—Bust of Charcot as a young man by Mezzara.

Anatomique which he had already held for some time. Cornil, his pupil, elected president in his place, proposed giving him a souvenir. "The proposition," according to accounts of the period, "was received, not only with enthusiasms by the members, both active and honorary, but also by the correspondents, both national and foreign. Very few subscriptions have ever been taken with such joy and interest in contributing." The souvenir in question was to be a medal with the portrait of Charcot, and its execution was entrusted to Vernon. The choice of artist could not have been happier; his medal of Charcot is among the best of his work. It is strong, sensitive, very true to life, and beautiful. Pierre Marie, who has a replica of the original, has had made an excellent photograph. . . . .

Another medal representing Charcot wearing his professor's cap was made by the daughters of one of his intimate friends, the Misses Casella, two talented artists who each year come to spend several months at the family estate of Charcot, and who, with his own daughter, Jeanne, have added to the decorative works with which the house is ornamented.

At the Salon of this year was exhibited a bronze plaque of Charcot. It is the work of a sculptor already renowned, Morlon, who, without having known Charcot, was so intrigued by his impressive face that he tried to model him. He has known how to reconstruct him and to give him grandeur.

In painting there exist several portraits of Charcot. None equals the sculptures. The earliest is in the old hall of the *Charité* and dates from the time when Charcot was at the close of his internship. It is no more than a sketch; but one finds on this young profile, very pure, the energetic traits which were accentuated with age, and already that gravity which was always the dominant note in Charcot's expression.

A painter whose name is today almost forgotten, Tofano, attained toward the end of the last century almost worldwide fame through a picture called Alone at Last, representing a young bridal couple finding themselves finally *tête à tête* after the marriage ceremonials. Tofano was one of Charcot's friends; to show his gratitude for Charcot's generosity, the artist painted his portrait in water colors in his professor's garb. This work, which is dated 1891, is not without merits; the harmony in reds, the fine sheen of the satins and silks appeal agreeably to the eye, the pose is noble, and, if one hand is perhaps too plump, we have the fineness of the fingers which is lacking in the statue of the Salpêtrière.

To help another artist in time of need, Charcot, not until after much persuasion, consented to have his portrait done in the robes of the Institute. This is also a water color, but with a smaller canvas; it had for Charcot merely the value of a good deed done.

The portrait of Charcot which is perhaps the most widely known is that which figures in the picture of Brouillet entitled A Lesson at the Salpêtrière. The picture represents an actual happening. It was in 1888 at the time when Charcot's course on hysteria attracted to his amphitheatre, not only a large number of doctors, but many of the curious with whom he never had any sympathy. The scene represented by Brouillet shows all the happenings in the lessons on nervous affections and diseases of the brain, spinal cord and nerves. It gives us an exact picture of the teaching of Charcot. He is represented standing, stooping slightly, indicating with a sober gesture the patient supported by his clinic chief (it was then Babinski). Around him are grouped his old pupils, his interns. One recognizes there Bourneville, Gilbert Ballet, Pierre Marie, Gilles de la Tourette, Jean Charcot, etc. And some frequenters of his lessons, Aibot, Paul Arène, Philippe Burty, etc. The plainness of the walls of the amphitheater, the rapt attention of those present, the great simplicity of the master, give to this scene an atmosphere of seriousness. It corrects, or in any case, disconcerts, those who, on the word of malicious talebearers, have imagined that the courses in the Salpêtrière served as the pretext for theatrical exhibitions, and that Charcot played the part of leading man. Absurd notion, the fruit of ignorance and envy! For, if Charcot did show himself to be desirous of introducing into his teaching everything that could reach the eye, no one was more averse than he to any form of showing off.

Finally Charcot and the engravings of him. One of the best of these is without doubt the aqua fortis of Paul Richer, who was for a long time his laboratory chief at the Salpêtrière. Charcot knew how to appreciate Richer, for he understood all his teaching could mean to a pupil who was later to attain fame not only through his work in anatomy for artists, but as a draughtsman, sculptor and medalist. In return, Paul Richer has perpetuated the features of his master. The portrait engraved by him will always remain one of the most sincere representations of this great personality. He is serious, he is grave, he is true.

Another engraving in aqua fortis represents Charcot dressed in his professor's robes. It is by Desmoulins. The drawing is free and vigorous, but the pose is a bit theatrical. Desmoulins has also included Charcot in an engraving depicting a number of contemporary physicians: Potain, Millard, Damaschino, Gilles de la Tourette, etc. The likeness and the expression are admirable.

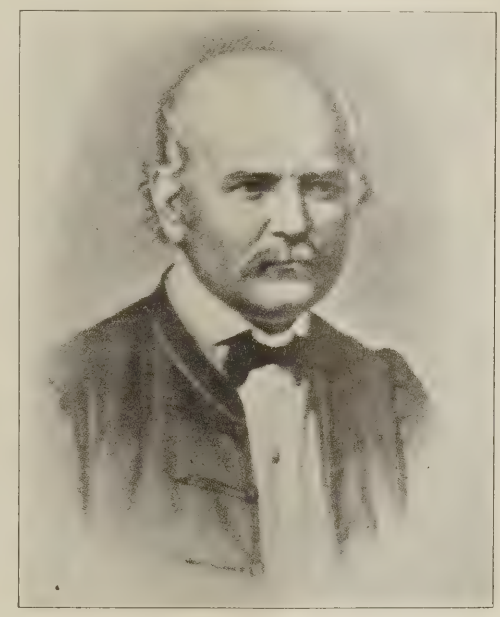
Most of these works of art may be found together in the country house where Charcot passed his vacations, in the Quartier Saint James, at Neuilly sur Seine. It is the home today of his son, Jean Charcot, who was one of his last pupils, and who, among the cruises which have made him famous, has taken upon himself the task of putting into a frame loved by his father, souvenirs of him and his life and work. If science is grateful to him for this, we now realize that art is none the less so.

Contributors to the Science of Medicine

Ignaz Philipp Semmelweiss

In the history of midwifery, which contains many dark pages, there is one name which shines refulgently and that name is Semmelweiss. While obstetrics, and gynecology too, lag behind other branches of medicine and surgery, obstetrics would be in a much worse position had it not been for the discovery by Semmelweiss of the true etiology of puerperal fever and the application therefrom of a logical method of treatment.

Perhaps in the whole history of medicine there are only two instances of discoveries which have brought about direct and immediate saving of life and prevention of suffering, the discoveries, respectively, of Edward Jenner and Ignaz Philipp Semmelweiss. It has been the fate frequently of men who have opposed traditional views which have upset the complacency of the followers of routine that they have been misjudged and sometimes deliberately misrepresented and slandered by their contemporaries. This has been the case oftentimes in medicine. Revolutionary ideas, even if they promise to lead to great benefits to the human race and the alleviation of suffering, are seldom if ever popular. It has happened that discoverers in medicine and surgery, and in modern times, too, have been subjected to indifference, obloquy and persecution.



IGNAZ PHILIPP SEMMELWEISS

Semmelweiss is a conspicuous example of this kind of treatment which embittered his life and helped to drive him insane. The story of his life and his doughty deeds are not well known to the English speaking medical profession, in spite of the fact that an international statue of him was unveiled in Buda-Pesth in 1906.

Ignaz Philipp Semmelweiss was born about the middle of July, 1818, at Ofen on Buda, now recognized as part of the great city of Buda-Pesth, the capital of Hungary. His father was a well to do shopkeeper and his mother, Theresa Müller, was of the same class. According to Tiberius von Gyory he was neither a German nor an Austrian, although after his death and when his fame was firmly established Germany laid claim to him as one of her sons. In the words of Sir William Sinclair of Manchester, who wrote his life, "Semmelweiss was a true Hungarian by birth, temperament and education, and he and his brothers proved in the troubulous times of revolution and civil war that they were Hungarian patriots who could make great sacrifices for the Fatherland."

The boy Ignaz went to an elementary school where he learned little, education being at a low ebb in Hungary at the time. The children of the Hungarian-German community had to learn two languages and it is stated that Semmelweiss learned neither properly and could never read or write as a well educated man. His further education in arts was as defective as that of the elementary school and he, therefore, began his medical education with the disadvantages or advantages of not being crammed with facts, many of them useless, which is often the lot of talented boys when at school. He had an open mind free from prepossessions and not disciplined to bow to tradition and authority as the minds of most of his antagonists of the future who had been trained in the rigid German fashion.

After passing two years at the University of Pesth engaged in the study of philosophy, he betook himself to Vienna and entered as a student of law at the university. He soon tired of law and at the age of nineteen registered as a student of medicine, going through the usual courses. He spent the second and third years at the University of Pesth; the remaining years of undergraduate study were passed in Vienna.

He is said to have been an industrious student, but brimming over with mental exuberance and physical activity. In March, 1844, Semmelweiss had passed all the examinations for the degree of doctor of medicine, but was prevented from taking his degree then on account of the sudden death of his mother. However, he obtained his degree in April, 1844. He worked then especially hard for the diploma of master of midwifery and on August 1, 1844, he was made Master of Midwifery. As he says in the introduction to his work, the *Etiologie*, "On July 1, 1844, I announced myself to the director of this Clinic as aspirant for the post of assistant, the first time a vacancy should occur. On July 1, 1846, I definitely assumed the duties of assistant at the First Obstetric Clinic, but I had to resign in October in favor of my predecessor, Dr. Breit, who had obtained a two years' extension of his appointment."

However, Semmelweiss during the time he was waiting for this post turned it to good effect. He had free access to the practice of the Clinic without being tied down to routine duties and he availed himself of these opportunities to the utmost. Not having the time to attend the Gynecological Clinic, he

examined the bodies of women who had died from gynecological diseases or operations and owing to the friendly interest of Rokitansky, the world famed professor of pathology in Vienna, he was able to obtain abundant material.

It may be said that then, as up to the time of the great war, Vienna was one of the best medical and surgical centres of the world, and had a large and well organized Lying-in Hospital. Semmelweiss took on the duties of first assistant at the First Obstetric Clinic towards the close of 1846, and while busy and contented worried greatly over the cause of the frightful mortality from childbed fever among the patients of the Clinic. In the year 1846 there were 460 deaths in the First Clinic and 105 deaths in the Second from puerperal fever alone. Before Semmelweiss various opinions prevailed as to the etiology of puerperal fever.

According to the most generally accepted doctrine there were two etiological factors; one external acting from without, the other internal, depending upon the condition of the organism during pregnancy and parturition, and whatever changes of nomenclature were introduced and whatever more or less obscurely expressed opinions became most prominent and generally accepted in a generation, we always find these two etiological factors at work in producing the phenomena of the malady. Gordon, of Aberdeen (1795), alleged that puerperal fever was an erysipelas of the bowels and peritoneum. Indeed, by the middle of the nineteenth century the almost universal belief in Great Britain and America was that erysipelas in the puerpera and puerperal fever were identical maladies. Again there was the "variable" theory of puerperal fever enunciated by Eisemann in 1837. That puerperal fever was disease *sin generis,* all the zymotic diseases were supposed to be capable of assuming the form of puerperal fever while concealing even their most characteristic features. In Great Britain where the most rational pioneer opinions on the subject had developed, there was a general belief in a contagium.

The supposed external causative factors were still more confusing and vague. Certain alleged influences of an atmospheric, cosmic, telluric nature bulked large in the minds of a part of the profession as external factors. Denman was among the first in Great Britain to express the opinion that puerperal fever was conveyed infection, but as Sinclair in his *Life of Semmelweiss* says, "his views were by no means clearly expounded."

There was a general belief, almost up to the time when Semmelweiss made public his doctrine, that the pregnant and puerperal woman was a thing unique in nature. Virchow in 1861 and Barnes in 1875 supported the theory of a spontaneous origin. In short, puerperal fever was considered to be as a disease something peculiar to pregnancy and the puerperal state.

The situation as regards the etiology of puerperal fever was chaotic in a high degree and the results of this ignorance were appalling at the time when Semmelweiss began to study the question seriously. It may be noted that at first the Hungarian pioneer was a milk fever epidemicist, and had far to travel to the doctrine of a decomposed animal organic matter directly conveyed to the genitals of an individual patient as the only etiological factor. But when he had completely mastered his discovery, or his discovery had mastered him, he was able to place erysipelas in its proper position in relation to puerperal fever, as a producer merely of decomposed animal organic matter.

As Sinclair has pointed out, "The modern universally accepted doctrine of the etiology of puerperal fever is that puerperal fever is a wound fever, and wound fever is wound poisoning. The supplementary doctrine is also universally established except for a mere logomachy, viz., all infection comes from without.

It was during Semmelweiss's second term as assistant in the First Obstetric Clinic that he made the discovery. Proceeding on the ground that it was the cadaveric material adhering to the hands that caused puerperal fever and that if in obstetrical practice the hands were perfectly clean, then the disease could be prevented to the extent to which it originated by the presence of cadaveric material on the examining fingers.

Finding further that washing the hands with soap and water failed to remove all the cadaveric particles he began in May, 1847, to employ chlorinated lime with which every student was required to wash his hands before making an examination. There was a marvellous reduction of mortality in the First Clinic, as a matter of fact, in March and August, 1848. No death occurred among the patients. On the other hand, in the Second Clinic the rate of mortality went on as usual, although owing to the fact that in the Second Division the patients were seldom examined and tended always to keep out puerperal fever.

It was then discovered that not only cadaveric particles adhering to the hand, but that putrid matter derived from living organisms produced puerperal fever. And again that atmospheric air might convey the decomposed organic matter which produced puerperal fever and henceforth patients suffering from wounds or diseased joints in which such matter was present were isolated.

The discovery of the causation of puerperal fever was now complete. In the *Etiologie* and the *Briefe* Semmelweiss makes frequent mention of these three sources of infection. It should be explained that Klein, the professor of obstetrics in the time of Semmelweiss, taught his midwife pupils by practice on the cadaver, which, of course, accounted for the cadaveric particles adhering to the hands. The practice of making postmortem examinations was universal in Austria at that time.

In July, 1855, Semmelweiss was appointed professor of theoretical and practical midwifery in the University of Pesth. In June, 1857, after settling down to the life in Buda-Pesth of a patriotic Hungarian citizen, Semmelweiss, thirty-five years of age, married a young woman of eighteen.

In Europe generally the doctrines of Semmelweiss met with but little support. This was due partly to the jealously and narrowmindedness of many of the professors of obstetrics and partly to the lethargy of Semmelweiss himself. He thought that his views had been proved and should rest on their merits. In Great Britain and Ireland the doctrine was received generally with favor. In 1857 Semmelweiss resolved to prepare and publish a book on the subject next his

heart and in October, 1860, the *Etiologie* was published. It has long been out of print and was becoming almost impossible to obtain, when in 1905 the whole works of Semmelweiss were edited by Tiberius von Gyory, privat-dozent in the University of Buda-Pesth, and published under the auspices of the Hungarian Academy of Sciences.

Semmelweiss in his later years interested himself in gynecology. He had always maintained that obstetrics and gynecology were so intimately related that they should be combined in teaching and practice. In his gynecological practice he acted on the same principles of antisepsis that he had introduced into the practice of midwifery. By the introduction into operative gynecology of antisepsis he was the forerunner of Lister. He was the first in Hungary to perform ovariotomy which sheds a light on the state of gynecology in that country. This was in 1863.

During the last two years of his life his mental condition caused his relations and friends much anxiety and on the last day of July, 1865, he was taken by his friend, Ferdinand Hebra, to an asylum in Vienna and detained there. It was soon discovered that a finger of his right hand had been injured probably as a result of one of his gynecological operations. The wound had become gangrenous, cellulitis spread along the arm, and after the formation of metastases it developed into pyopneumothorax, of which he died on August 19, 1865. The autopsy revealed extensive organic disease of the brain. The remains were first interred in one of the burying grounds in Vienna and it was not until the year 1891 that they were conveyed to his native place where they found a more becoming last resting place. It is only within a comparatively recent period that Semmelweiss has been given the honor which is his due. It is true that Dr. Oliver Wendell Holmes suggested in an essay published in 1843, *Contagiousness of Puerperal Fever*, that puerperal fever was contagious, but Semmelweiss worked out the subject practically. It was his whole life, for which he fought and died and he really solved the problem of its etiology. Semmelweiss lived and died a martyr to science but his labors and sorrows have not been in vain. He revolutionized the practice of obstetrics, which is his monument.

A Pope as Physician

T. J. DOWNING, M.D.

New London, Mo.

In the Medical Journal and Record, December 3, 1924, page 557, there is an article entitled A Pope as Physician, from which I quote as follows: "For Church and political reasons a conclave of Cardinals, in the year 1276, elected to the Papacy a Portuguese Physician, Petrus Hispanus, already Cardinal—Bishop of Tusculum, as Pope John XXI. According to nearly all writers of ecclesiastical history, he should have been named John XX; since there were only nineteen Johns before him."

Some years ago an old book came into my possession by way of the second hand book store route; three 12mo volumes; page capacity 1436; title long. But I will venture.

"Histoire Chronologique Des Papes, des Empereure Des Rois, Des Electeurs de l'Empire et Autres Princes, qui ont regne en Europe despuis la naissance de Jesus-Christ jusqu' a present. Avec un Abrege Historique a chaque Article, ou l'on voit Ceremonies de l'Election & Couronnement des Princes electifs, la nature du Gouvernement, les Droits, Privileges & Prerogatives de chaque Etat & de chaque Prince, &c. Par Mre. P. B. M. Malbranche Ecuir, ci-vant Licencie aux Universites d.Oxford & de Cambridge, &c. Chez Jean Leonard, rue de la Cour. MDCCXLI.

As to the quotation in the Medical Journal and Record: "he should have been named John XX, since there were only nineteen Johns before him." As a matter of fact there were only eighteen Johns before him. In proof, quoting from the "Old-Book":

"985. Jean XV, succeda lui," John XIV, "l'an 985. Il maintint autant qu'il lui fut possible l'Eglise en paix, & n'oublia rien pour bien remplir tous les devoirs de son ministre. Il mourut le 7 Mai de l'an 996, apres 10 ans, 4 mois et 12 jours de Pontificat." Then follow Gregoire V, Silvestre II and Jean XVII, 996-1003. Thus John XVI is *apparently* missing. But as a matter of fact John XVI is not missing. Turning to page 70 Tom I, in List of "Anti-Papes" is the following: "997. *Jean XVI. faux Pontife, s'establit dans le Siege de S. Pierre l'an 996, ou 979. Ont dit qu'il etoit scavant, & qu'il avoit compose divers ouvrages. Il mourut le premier jour de Juin de la meme annee."*

Now as to John XX. John XIX was Pope 1024-1033. Then we jump to 1276 and find in the "Old-Book": "1276. *Jean XXI, nomme Jean Pierre, Cardinal de Frescati, natif de Lisbonne en Portugal, lui succeda," Adrian V. "le 13 Septembre de l' an 1276. Il etoit docte, saye & pieux. Il mourut le 20 Mai de l' an 1277, apres 8 mois et 8 jours de Pontificat."* Thus John XX is apparently missing. But as matter of fact John XX is not missing. Turning to page 71 Tom I, in List of "Anti-Papes" is the following: *"Jean XX. C'est ainsi que l' appellent quelques-uns, qui disent, que le Pape Benoit IX, se jugeant indigne du Pontificat, ceda cette Dignite a Jean Archipretre, qu'il faut distinguer du Pape Gregoire XI. according la Plus faine opinion."* Benoit IX succeeded John XIX and was Pope 1033-1044.

There are four Johns in the List of "Anti-Popes." Only two are numbered—John XVI and John XX. Thus the apparent gaps are filled. There must be a justification for thus numbering John XVI and John XX. It completes the list from John I—523 to John XXIII 1410. Notice old style French.

Editorial Articles

THREE MOVEMENTS

Three bowel movements a day are advocated by Dr. Fisk of the Life Extension Institute, and presumably he believes that this unusual liveliness of the gut will add to our span of existence. At a meeting of the trustees of that organization, ex-President Taft poked considerable fun at its director, saying, in effect, that he was well satisfied with the program of the institute, but wished to be excused from complicity in such activity of the bowels.

Lane has recently championed this frequency of evacuation and recommends of course that constricting and obstructing bands be removed by the surgeon in order that such activity will be unrestricted.

Verily the colon, which formerly had a rather peaceful day of it after not more than one evacuation, has been much set upon since the days of Metchnikoff, and, with all the theories which have been advanced against its sluggishness, or which threaten its very existence, we know of no actual figures to show that it is so at fault. On the contrary, there are statements that in cases where it does not empty itself for days the person may be in good health.

Perhaps its degree of activity needs to depend on what it contains. It is unfortunate that we have statements based on so little real knowledge but resting wholly on opinion or on a limited experience. If we would all be better off by defecating three times a day we certainly ought to be doing so.

In no field of physiology (normal and pathological) are we more lacking in knowledge than in that of what actually takes place in the course of the passage of food through the alimentary tract, and yet no ailments are nearly so common as those which have to do, directly or indirectly, with dyspepsia. It was not until recently that we had much knowledge of the time which it takes food in general to pass through various sections of the digestive tract, and, in fact, we know nearly nothing yet as to the time of passage, or what really occurs in the handling, of individual foods. It has long been known that there is a selection of foods in the stomach—that certain things are held for an hour or two longer than others, but we do not know about selection which may occur farther on. We cannot tell a patient whether it is the handling of the food of his supper, dinner, or breakfast which has gone wrong, or even if it was the meal of the day before which has been making trouble for him.

It is to be hoped that more thorough investigations will be made along these lines, for there is promise of blessing to a host of mortals through such studies and it is not impossible that the origin of many diseases which seem unrelated to these daily disturbances that make life miserable though they do not kill, will be cleared up.

In the meanwhile most of us will hardly find time for those three movements of an organ which was developed for the purpose of serving as a receptacle which might be emptied at convenience and on natural inclination.

LO! THE POOR MALE!

If there has been one thing on which man has congratulated himself as being superior to women, it has been on the matter of clothing. A generation, even a decade, since, it would never have been dreamed that he could ever have been recommended, and that by members of his own sex, to follow the example of his sister in his habiliments. The unexpected has happened, however, and women, if we can trust our autocritics, now lead in the hygiene of clothing. Strange to say, they have done this by their own unclothing or by gestures in that direction.

Here cometh a German physician, E. Friedberger, who urges fervently that man reform, especially in his summer clothing, and follow the example in rational garmentage recently given by women; and an English physiologist, Leonard Hill, would have us cast aside the close collar and long trousers, emulate the low blouses, short skirts and artificial silk stockings of girls, and so let in more light, especially ultraviolet light, which is said (and we can well believe it) to penetrate such gauzy nether attire. Since it is only by superior health and vigor that man can hope to regain his supremacy, or keep what little ground remains, it is high time he was following the advice of these farseeing gentlemen.

We still have one point of vantage, however, or rather women, even young women, still have a handicap which lends encouragement to the opposite sex, for if we can trust the argument of a noted exponent of physical education, they are wearing one article of apparel which impedes their progress to complete dominance. This gentleman, speaking of bad posture in school girls, blames much of it on the brassiere which, he asserts, forces the breasts down and often causes serious deformities. Maybe it does, but we alway supposed it supported the breast and had, if any, an effect for good upon posture. We will leave it for the reader to judge. Happily man is not much in need of this particular harness and it is not likely he will ever add this to other causes of his growing inferiority complex.

The brassiere probably makes for good posture rather than bad, but if it is ever proved to be in the least a handicap, we are sure that woman, in her present mood, will fling it aside.

There is one feature in regard to clothing in which we might imitate and emulate the ladies and that is in the wearing of colors. We display a small splotch under our chins, but that is as far as we have gone in this direction. Our ancestors from a century ago and back into earliest historic times loved color and seemed happier and healthier in mind than we, the wearers of black and grey, who make so drab and melancholy a mess of life.

THE TEETH OF ABORIGINES

The teeth of the Egyptians of pyramid building days show in their mummies an extensive amount of disease. And, according to Keith, such disease is to be found in the remains of very early man, though these remains are so few as to give us no notion of the frequency of dental pathology. It is interesting to learn that some tribes of American Indians of the earlier periods who had not adopted the ways of their white conquerors were very superior to them in the way of their teeth. There are Indians and Indians, however, and some tribes were far better in this respect than others.

The investigation was made by R. W. Leigh, a dental surgeon, captain in the Dental Corps, U. S. A., and associate professor in the Georgetown University Dental School, of the condition of teeth in the skulls of the following Indians: Algonquins in Kentucky; Sioux; Arikara and Zuni.

The Algonquins were a sedentary people who lived by hunting and fishing and gardening. Maize, squashes, and probably beans, with fruit, formed their chief diet. The tribe had probably never been in contact with Europeans.

The Sioux were nomads and nearly wholly meat-eaters, chiefly of bison. The wild cherry, plum, strawberry, and prairie turnip were used to some extent. They were of fine physique. Their mode of life had not been affected by the white intruder.

The Arikara were semisedentary, raising beans, corn, and squashes. They also ate meat (bison) and fish.

The Zuni were a sedentary agricultural people, living in communal buildings. Their diet was largely vegetarian and meat formed only a small part of their diet. Their diet and mode of life was most nearly related to our own.

In the first group the dental arches were well developed. The "dental characteristics of the Sioux elicit considerable admiration," the teeth being large, well formed and even free from developmental or acquired disease. The teeth of the Arikara resembled those of the Sioux. In the Zuni skulls the "denture is the smallest and least perfect of any of these tribes."

Attrition or wearing away of the hard parts of the teeth was remarkably frequent in the Algonquin skulls, probably from chewing maize mixed with the particles of stone on which it was ground. The teeth of the Sioux showed little wear until after fifty years of age.

Caries was infrequent in the Algonquin. There were only twenty-eight small lesions in thirty per cent. of skulls. These were all in persons well advanced in life. The Sioux were least susceptible; in ninety-two crania "there were but ten with carious lesions, most of which were quite simple." There was but one alveolar abscess. Twenty-eight per cent. of the Arikara showed caries and in the Zuni skulls there was seventy-five per cent. Many teeth were lost early in life in this latter group which is in contrast with the others.

The Sioux seem to have been freer from peridonclasia (pyorrhea) and periapical lesions were less common, though they existed in sixteen per cent. of the skulls of these Indians.

THE MODERN NOVEL AS AN INDEX OF THE PUBLIC MIND

If one is to take at their face value the best sellers of today, the conclusion must inevitably be reached that the mind of modern man is a pretty rotten affair. Pornographic heroes and lewd heroines strut through the pages mouthing empty banalities about freedom from the old bondage. Greasy philosophers whose main object in life seems to be living at the expense of someone else, utter weird conclusions about existence untrammelled by the dictates of decency. Chastity, if one is to believe these books, has ceased to exist except in the aged and repulsive, morality is no longer smart, and real honesty a handicap to the genuine expansion of the soul. The modern girl is pictured as a sort of a cross between a courtesan and a Parisian fishwife forever screaming *a la lanterne* for all of the clean and noble things of life. Nowadays it isn't smart to read good, clean books and as a result a sort of cubist literature devoid of punctuation and filled with ghastly inaccurate pictures of life crowd the book stalls.

To the thinking person, especially if he has any interest in public psychology, all of this presents an interesting problem. The practitioner of medicine wonders what effect these mental distortions are having on the psychology of his clientele, and the public health worker is led to ponder over the effect

this has upon the spread of venereal infections and the insanity rate. If these books are to be believed, the world is making a direct onslaught on chastity, the cornerstone of civilization, and a decadence of the human race has set in.

It is hard to believe that such a condition of affairs exists. Victorian prudery has gone by the board and perhaps the very knowledge which the young people of today are getting may be the means of combating a great many practices which have hitherto influenced badly the health of the race. In every age there has always been a number of salacious cults whose stock in trade has been sheer nastiness, but such people have never been in the majority and have never very greatly influenced the thought and action of their time. The pure of heart, the restrained in action and the conservative in morals have, in the end, always dominated.

It is interesting to speculate as to the cause of this casting away of restraint. If we are to take Mr. H. G. Wells' latest book, *Christina Alberta's Father,* as an allegory, the world is like Mr. Preemby, who married into the laundry business and was utterly repressed for twenty years by a wife whose fear of her own sin made her brutally apprehensive lest her mate might sin also. Upon her death her husband, thus rid of all his inhibitions, expands his daydreams to a point at which he imagines that he is the king of the world. Fortunately his introspection remains and before his death he recognizes that his dream is but a phantasm. The explosion of the war shattered many of the world's inhibitions and perhaps man is but dreaming for a while that he is king of the world. Fortunately for him, much of this insight still remains and he will find his way back to sobriety, decency and selfcontrol.

NAMING THE BONES

Humanity, even that portion of it which prides itself on being "scientific," is prone to follow a course of conduct which it deems wise for a season —often a protracted season—and then suddenly to reverse its judgment as to the wisdom of its past practice. If there is ample reason why it should thus change its mind, it certainly should do so, for consistency in following a wrong course is far from being a virtue; but the exhibition of such weathercockishness should make us humble with regard to any human judgment and cause us to question whether the newly adopted and perhaps diametrically opposite course is altogether right or any more certain of leading us where we wish to arrive than was the one we have just forsaken.

For years considerable time and pains were employed in teaching children the "names of the bones" and, incidentally the names of less evident parts of the human anatomy together with some facts or opinions as to how the organs were made and what they were made for. Just at present the "naming of the bones" is frowned upon as being of no consequence for the reason that the information conveyed has little influence in improving the health of the child. With the veering of the course of the ship of education the tendency is to throw overboard any oldfashioned instruction in the make up and working of the human machine.

This change of policy has been the result of a new attitude toward, and the adoption of, better methods in handling hygiene, and we are prepared to admit that mere information about physiology, no matter to what extent it may be acquired, may have no effect whatsoever in affecting the health of the student, just as a course in ethics may leave him no better in his general conduct. It is certainly possible to know all that is known about the bodily machine and even about the laws of hygiene and yet to put none of this knowledge in practice though one may question whether such knowledge does not have some effect for good. On the other hand, it is possible to be abundantly healthy without any book knowledge of these subjects or any teaching by the schools. The wild animal does not know the names of the bones and he could not tell a carbohydrate from the cerebellum by name, nevertheless he is better at practising health habits than his wiser cousins who go to school to school teachers. He has his teacher, it is true, and Nature is a firm disciplinarian but he knows no names, nor can he enumerate the health habits which he practises.

Since the days of Adam the naming of things has been an important business of man. In fact it seems to have been the sole occupation of our first parent. And when man has named a thing or learned its already given title he "knows it" or thinks he knows it. We see a new flower about which we are curious until we have learned that it is an "orchid"—but having learned this, we "know it" and are content. We hear of a new planet and having heard what it is "called" we speak of it familiarly. Our books and our libraries are made up chiefly of names. Writing to his imaginary friend in Persia, Montesquieu remarked of the libraries of Paris that he had discovered many huge volumes on the subject of medicine made up chiefly of long names which "neither cure the patient of his ills nor relieve the physician of his ignorance."

Education in the ordinary sense of the word—"mental education" (if we can any longer pigeonhole this functioning of nerves, muscles and sense organs) —consists chiefly in the learning of the names of things and acquiring information about the things

named. Since there are so many objects to be thus "studied" it behooves the educator to make a choice of those to be studied—of the things, the names of which are to be learned in school. There are the stars and planets; the continents and oceans; the countries and cities; the emperors of Rome and the kings of England; the great generals and the great statesmen; the great writers and the great artists; the great books and great pictures; the names of the animals of the arctics and tropics; the exports of Brazil and the products of California. But all we have mentioned could be learned in a few days and the teacher must go into details.

Opening at random a high school textbook on history, we find the following words: "Pericles favored a policy of hostility towards Sparta, and induced the people to construct two long walls from Athens down to the shore so that they could reach the port of the Piraeus without damage from a besieging army." Doubtless this is very important or was to the author, but some of the things named are a long way off in time and space.

A textbook on science tells that "water, as it passes through the air, absorbs a small amount of carbon dioxide gas, making weak carbonic acid" (very weak indeed. If it were only strong enough for "soda water"!). There are pages about engines with enumeration and descriptions of cylinders, piston rods, accentrics, valves, gears, etc. There happens, also in this particular book (what is besides the point) the statement that "a strong constitution is the most effective barrier again disease germs," which is, unfortunately, untrue. George Washington prided himself on his strong constitution, but he was successfully attacked by disease germs about as many times as any one could be and survive, and he was finally carried off prematurely by an attack of quinsy. Had Roosevelt been immune to malaria and other infections he would doubtless be living today. This book was written by a professor of chemistry. But we are straying from our topic.

Opening the most attractive covers of a new geography (in education we are always viewing if not "new" heavens, at least "new" earths) we find that the pupil is expected to inform himself as follows: "In the silvas most of the animals are adapted for living on trees, and hence, with the exception of the tapir, jaguar, anteating bear, and boaconstrictor, they are rather small. Among the smaller animals are peccaries and anteaters." Certainly no place to hunt big game.

Now we may be mistaken but it seems to us that, both in time and place, man ought to be most concerned with the things nearest at hand and most vital to his well being; and we are certain that our bones are very intimate objects and that they are very essential for our well being, and since all of our knowledge of things consists, originally, in learning their names we believe the names of the bones better worth learning than the doings of the Athenians or the amount of carbon dioxide in the air or the sort of animals to be seen in South America. But bones, as we living things have them, are not dead things, and they inspire devious inquiry as to where they came from? What limits their growth? The purpose of their various humps and hollows? What is going on inside them? and other fascinating questions. One query, What are they "made of?" opens at once a chapter in chemistry of the utmost importance in future parenthood since from ignorance on the subject a considerable percentage of present day offspring are affected by rickets, a disease due to ignorance of the materials for the making of bones. In really "naming the bones," with the help of someone who knows them we begin to appreciate the miracle of our own bodies and we may come to exclaim with Sir Thomas Browne, "We carry with us the wonders we seek without us; there is all Africa and her prodigies in us; we are that bold and adventurous piece of Nature, which he that studies learns in a compendium what others labor at in a divided piece an dendless volume."

The study of the human body would seem to stand first in importance among all possible subjects and for practical importance, for it still remains the informational basis of hygiene. Besides, there are a great many who agree with Spencer that "for discipline as well as for guidance, science is of chiefest value," and this science comes nearest home.

In the general study of the human body the bones (using the word specifically) are an excellent starting point. Oliver Wendell Holmes when teacher of anatomy expressed himself as enjoying the "dry parts" but not the "wet parts" of his subject and, with the exception of a few enthusiasts who exclaim over "beautiful specimens" of liver or lights, most of us have, at all ages, an aversion to exhibition of the soft tissues of the human machine. A skeleton or a piece of it, is not disagreeable nor forbidding, on at least second acquaintance, and, while dry in one sense, it contains the gist of all the fascinating story of the human organism from its one celled beginning. A mighty monster of antiquity can be reconstructed by the cunning paleontologist from a single bone and a capable teacher can do as much and more for the human body in an appeal to a class through a bone of one of their own species.

It was the opinion of Melanchthon that "it is disgraceful for a man not to know the structure and composition of his own body," and it might appear that while we are learning the names of everything else under the sun, often in more than one language,

we should give adequate time and attention to the naming of the bones. In fact it would seem as if one of the most certain tests of intelligence should be the extent of our knowledge of the machinery and management of our own bodies.

Obituary.

RICHARD HICKMAN HARTE, M.D.

Philadelphia

News reached New York on November 15th of the death in Vicksburg, Miss., on the previous day of Dr. Richard Hickman Harte, a well known surgeon of Philadelphia.

Dr. Harte was born in Rock Island, Ill., on October 23, 1855. He received his degree in medicine from the University of Pennsylvania in 1878, and subsequently spent several years abroad continuing his professional studies in the hospitals of European cities. Upon his return to this country, he was made assistant demonstrator of surgery at Pennsylvania. Among other positions and posts of honor held by him were those of emeritus surgeon, Pennsylvania Hospital; consulting surgeon at St. Mary's Hospital, St. Timothy's Hospital, Bryn Mawr and Abingdon Hospitals; adjunct professor of surgery at the University of Pennsylvania, former director of Public Health and Charities in Philadelphia, former president of the American Surgical Association, of the College of Physicians and Surgeons, Philadelphia, and of the Philadelphia Academy of Surgeons, fellow of the American College of Surgeons, and of the *Société Internationale de Chirurgie*. For many years he was editor of the Transactions of the American Surgical Association. He was the author of the *Handbook of Local Therapeutics*, and made many contributions to various journals.

Dr. Harte served as surgeon with an ambulance corps in 1918 in Paris, and organized Base Hospital Unit No. 10 and went overseas as its commander. He was mentioned in the dispatches of General Haig and received the British Order of St. George and St. Michael, and the Belgian Order of King Leopold bestowed for special service rendered during the war. Ireland made him a fellow of its Royal College of Surgeons for conspicuous service to the British forces.

LUNCHEON IN HONOR OF SIR ARBUTHNOT LANE

On Wednesday, November 25th, a luncheon in honor of Sir William Arbuthnot Lane, the well known British surgeon, was given by Dr. William Seaman Bainbridge, of New York, at the Union League Club. There were present sixty-five physicians and surgeons.

In introducing Sir Arbuthnot Lane, Dr. Bainbridge, who acted as toastmaster, referred to the fact that he had known the London surgeon for more than twenty years and at about that many years ago had given a dinner in his honor on the occasion of one of his first visits to New York. Dr. Bainbridge also drew attention to the originality as a surgeon of his guest, pointing out that he was essentially a blazer of the trail. Many years ago he devised a new method of doing a mastoid operation and was the pioneer in plating fractures, besides showing the way in other surgical procedures.

Sir Arbuthnot Lane then presented his views on chronic intestinal stasis, declaring that the majority of diseases with which mankind was afflicted were preventable, and of such preventable disorders intestinal stasis was the most common. He insisted that it was a disease of civilization from which primitive races were free and that civilization was menaced by it. Indeed, the populations of civilized countries were destined to die from chronic diseases and cancer unless the gospel of health, good food, good habits, good air and exercise, could be successfully promulgated.

He then outlined the objects of a new association in England, the New Health Society, which is being organized and over the first meeting of which in London he is to preside on December 11th. Its members are politicians, research workers, and some of the leaders of medicine and science. The objects of the New Health Society are: 1, To spread the knowledge of the newer discoveries of science which concern the preservation of health and the prevention of disease; 2, to teach the advantages of right food, fresh air, sunshine and exercise through the medium of newspapers, pamphlets, books, wireless and lectures; 3, to cooperate with local authorities, schools, churches, medical officers of health, trade unions, nurses' and other women's organizations, welfare centres and every other available agency; 4, to influence caterers and heads of schools, colleges and other institutions to provide pure, natural and unspoilt food; 5, to secure improvement in the quality and supply of milk, fruit, vegetables, bread and other foods by urging the best methods of production, storage and distribution; 6, to prevent profiteering in food, and to improve and cheapen transport in order to reduce food prices; 7, to adopt every available means for preventing the contamination and adulteration of food and to promote legislation for this purpose.

At the conclusion of Sir Arbuthnot Lane's address a resolution expressing sympathy with and support of the new society's aims was proposed and carried.

United States Senator Royal Copeland spoke of the most enthusiastic terms of the objects of the new society and said that he would use his utmost endeavors to have a similar scheme adopted here. He pointed out the pressing need for the education of the masses in all concerning disease and especially in the prevention of the same. Dr. Robert T. Morris, Dr. William B. Coley, and Dr. Charles H. Chetwood also spoke briefly. Several physicians present suggested that the aims of the Gorgas Memorial were similar to those of the new society.

Among those present were: Dr. A. Judson Quimby, Dr. Edward Kellogg, Dr. J. M. Lynch, Dr. Anthony Bassler, Dr. William Sharpe, Dr. J. Eastman Sheehan, Dr. I. Bern Hirsch, Dr. Asa B. Davis, Dr. Erastus Mead Hudson, Dr. Henry W. Freudenthal, Dr. W. Hall Hawkins, Dr. Gregory Stragnell, Dr. M. W. Thewlis, Dr. William H. Newcomb, Dr. Louis Faugères Bishop, Dr. F. M. Jeffries, Dr. H. Dawson Furniss, Dr. Joseph F. Saphir, Dr. A. J. Rongy, Dr. James N. West, Dr. Lewis Gregory Cole, and Dr. Ross McPherson.

News Items.

Psychiatric Clinic.—Northwestern University, at Evanston, Ill., is supervising a free clinic for mental and behavior disorders, as a branch of the clinic in Chicago. Dr. Herman Adler, director of the Institute of Juvenile Research, will provide a psychiatrist for the clinic.

Hygiene in Cotton Mills.—The Public Health Service is undertaking a study of hygienic conditions in and around the cotton mills of Greenville, South Carolina, and that vicinity. The work is planned to extend over a two year period.

Medicine in Germany.—A warning against taking up the study of medicine for the next few years, on account of precarious returns for the expense of training, has been issued by the Prussian state authorities. This action, however, is stated by the *Klinische Wochenschrift* to be sponsored by the officers of the organized medical syndicates.

Resolutions on Health Officers.—The Chicago Medical Society has adopted resolutions against the appointment of laymen holding a D.P.H. degree as health officers instead of physicians holding an M.D. degree; the action mainly directed against the American Public Health Association, at whose annual meeting in St. Louis a paper was read favoring such appointments of laymen.

Gifts to University of Chicago.—A grant of $10,300 has been received from the National Research Council for studies on the biology of sex. There have also been received gifts of $3,000 from the National Tuberculosis Association for the study of nutrition of the tubercle bacillus; and $2,500 from the Carnegie Corporation, through the American Association of Museums, for a psychological study of museum fatigue.

Medical Study Tour to Europe.—The Travel Study Club of American Physicians, which was founded at the International Medical Congress at London, in 1913, is arranging a 1926 Study Tour to Oslo (Christiania), Stockholm, Copenhagen, Hamburg, (optional to Berlin and Munich), Cologne, Wiesbaden, Heidelberg, Strasbourg, Berne, Zurich, Leysin, Geneva, Paris and London. Dr. Louis L. Seaman, of New York, is president; Dr. Fred H. Albee, of New York; Dr. Edward B. Heckel, of Pittsburgh; Dr. John P. Lord, of Omaha, vice-presidents. Physicians of good standing are welcome to participate in this Study Tour to the limit of fifty, and for information should address the secretary, Dr. Richard Kovacs, 223 East 68th Street, New York City.

Hospital News.—A mass meeting was held by citizens in the locality, demanding the reopening of the old Williamsburg Hospital, of Brooklyn; an accounting of the endowment fund was also asked for.

St. Vincent's Hospital of New York, is planning a campaign to raise one million dollars.

The Wyckoff Heights Hospital, New York, is opening four new clinics—pediatrics, diabetes, dermatology, and obstetrics and gynecology.

A campaign was begun November 21st, by the New Rochelle Hospital, New Rochelle, New York, to raise $1,000,000 for expansion of the institution.

It is reported that the Henry Ford Hospital, of Detroit, has abandoned the flat rate system of charging for treatment. The new arrangement provides surgical fees up to $1,000, and medical charges up to $70 a week. A deficit of over two million dollars has arisen.

The University Hospital, of the University of Michigan, Ann Arbor, was dedicated November 19th, to 21st. Speakers at the formal exercises included Dr. Victor C. Vaughan, of Washington, D. C.; Dr. William J. Mayo, of Rochester, and Dr. William S. Thayer, of Baltimore. Clinics were held in the different departments of the hospital. Doctor Mayo also delivered the annual Mayo lecture, his subject being Splenic Syndromes.

Mr. John E. Ransom, superintendent of Michael Reese Dispensary, Chicago, has resigned.

The City Hospital of Indianapolis is to build a new surgical unit, at a cost of about $200,000.

The Nassau County Sanatorium, Farmingdale, New York, has started work on a building for seventy children, at a cost of $250,000.

The University of Virginia Hospital, Charlottesville, has opened a new clinic building. A child welfare clinic will be conducted with funds secured from the Commonwealth Fund, private contributions, and the University Hospital League.

Lister Ward Preserved.—The firm of Burroughs Wellcome have rebuilt in London the Lister Ward of the Glasgow Infirmary, which was dismantled a year ago.

Doctor Abel Honored.—Dr. John J. Abel, professor of pharmacology at Johns Hopkins Medical School, has received a reward of $2,500 for outstanding contributions to science, from the Research Corporation of New York.

Professor Bechtereff Honored.—The fortieth year of the scientific activity Professor Bechtereff of Leningrad, Russia, will receive official celebration on December 20th. Scientific material is being collected for publication in honor of the anniversary.

Medical Women's Scholarship Fund.—The Medical Women's National Association report that at present there are four young women studying medicine on scholarships provided by the association, two at school in Boston, one in New York, and one in Philadelphia.

Speech Training Clinic.—Dr. John A. Glassburg and Mrs. Edward Scripture of New York are in charge of special courses in speech training and the correction of speech defects, to be conducted free of cost at Greenwich House, a settlement in New York. The classes meet Monday from four to six.

Wellcome Medal Awarded.—The Wellcome Gold Medal for 1925 was awarded by the Association of Military Surgeons to Lieut. Col. Albert C. Carlton of San Francisco, for his essay on means and policies which will best enable this association to increase its membership and accomplish its patriotic objects as stated in its constitution.

Army Death Rate.—The general death rate in the U. S. Army for 1924 is computed at 3.83 per thousand, compared with 3.91 for the preceding year, the first time the rate fell below four per thousand. The death rate for disease in 1924 was 1.94 per thousand, the first time it has fallen below two per thousand. Suicide held first place as cause of death; tuberculosis, second; automobile accidents, third; and balloon and airplane accidents, fourth.

Regional Consultants in New York State.—The State Department of Health has appointed Dr. George Kosmak and Dr. Frederick W. Rice, both of New York city, regional consultants in obstetrics; and Dr. William J. Orr, of Buffalo, Dr. Arthur W. Benson, of Troy, and Dr. Hugh Chaplin, Dr. G. W. Graves, Dr. W. R. May, and Dr. Herbert Wilcox, all of New York, as regional consultants in pediatrics. The appointments are made in order to provide lectures and clinics in the postgraduate work being carried on by the medical society and the department of health of the State.

Personal.—Dr. Seymour Basch has been appointed clinical professor of gastroenterology to the Polyclinic Hospital of New York.

The joint annual meeting of the Newburgh and Poughkeepsie Medical Societies was held at Newburgh on November 17th. Dr. Smith Ely Jelliffe, of New York, gave an address on Psychoanalysis and Organic Disease.

Dr. Wilfred M. Post is visiting in New York City. Doctor Post is chief surgeon of the American Hospital of Constantinople.

Dr. Dean Lewis has been appointed professor of surgery at Johns Hopkins Medical School, and surgeon in chief to the Johns Hopkins Hospital.

Dr. Errett C. Albritton of Buffalo, New York, has been appointed professor of physiology at Chulalongkorn University of Bangkok, Siam.

Dr. Walter T. Dannreuther, professor of gynecology at the New York Post-Graduate Medical School and Hospital, was guest of honor at a dinner given recently. Dr. Charles Gordon Heyd presided, and Dr. John O. Polak and Dr. Samuel W. Bandler gave addresses.

Dr. Howard Fox has been appointed professor of dermatology and syphilology at the New York University Medical College, succeeding the late Dr. William B. Trimble.

Dr. Hideyo Noguchi of the Rockefeller Institute has received the honorary degree of doctor from the University of the Sorbonne, Paris.

Dr. Oliver R. Avison, president of the Severence Union Medical College of Korea, is visiting in New York. Doctor Avison originated a medical language in Korean, and translated *Gray's Anatomy* for his students.

Dr. Louis M. Warfield, formerly head of the department of medicine of the medical school of the University of Michigan, has located in Milwaukee.

Society News and Notes.

The Massachusetts Society for Mental Hygiene is sponsoring a course of fifteen practical lectures on the mental health of children being given at Boston University School of Education. J. Mace Andress, Ph.D., is director of the course, and one of the lecturers. Others are Dr. Douglas A. Thom, Dr. Karl M. Bowman, Dr. Ransome A. Greene, Dr. John D. McCarthy, Dr. Marianna Taylor, Dr. Abraham Myerson, Dr. Henry B. Elkind, Prof. Ernest R. Groves, Augusta F. Bronner, Ph.D., and John M. Brewer, Ph.D.

* * *

On the afternoon of Tuesday, December 22d, at four o'clock, Augusta F. Bronner, Ph.D., of the Judge Baker Foundation, Boston, will deliver a lecture at the New York Academy of Medicine on Juvenile Delinquency and Mental Hygiene. This lecture is one of the course being given at the academy under the auspices of the National Committee for Mental Hygiene, the New York State Committee on Mental Hygiene, and the New York Neurological Institute. On the afternoon of January 5, 1926, Dr. Arthur H. Ruggles, of Yale University, will speak for the same course on the subject, Mental Hygiene as a Preparation for College Life.

* * *

At the annual conference the latter part of October of the General Council of the United Kingdom Alliance of Great Britain held in Manchester, local option was advocated as the shortest way to reach prohibition, according to the *Manchester Guardian Weekly*. Mr. Leif Jones presiding, declared that there is now a more widespread interest in the temperance question than for many years past. On the other hand, the drink bill was rising, and he feared that with a revival of industry it might again reach the figure at which it stood the year after the war. Sir George Paish, who moved a resolution declaring that in view of the economic and financial position of the country, the suppression of the drink traffic would contribute greatly to national wellbeing, delivered a serious warning as to the shortage of world's food supply.

The Baltimore Medical Club of New York City held its semiannual dinner at the Waldorf Astoria on the evening of Saturday, December 5th. The address of the occasion was made by Dr. Lewellys F. Barker, of Johns Hopkins.

* * *

The regular monthly conference of the New York City Cancer Institute was held on November 27th. The discussion related to cases presenting intraperitoneal radium insertion, including carcinoma of the breast, the tongue, and the bladder; and intratumoral insertion of radium emanation and surgery in cancer.

* * *

The New York Electrotherapeutic Society met on December 2d at the New York Academy of Medicine. Dr. M. A. Lyons and Dr. Herman Goodman presented cases, and case reports were given by Dr. Sinclair Tousey, Dr. Victor C. Pedersen and Dr. Frank T. Woodbury.

* * *

The New York Society for Thoracic Surgery held its semiannual meeting the evening of Tuesday, November 24th, in the New York Academy of Medicine building. Patients were presented by Dr. Howard Lilienthal, Dr. Willy Meyer, and Dr. Harold Neuhof; case reports were given by Dr. Hermann Fischer and Dr. Ethan F. Butler; röntgenograms were shown by Dr. Franz Torek, Dr. Leon T. Le Wald, and Dr. Harold Neuhof.

* * *

The stated meeting of the New York Academy of Medicine was held in cooperation with the Section of Medicine on the evening of Thursday, December 3d. A symposium was held on the liver and gallbladder, in which Dr. Philip D. McMaster discussed the significance of urobilin; Dr. George B. Eusterman, of the Mayo Clinic, the present status of chronic cholecystic disease, and practical aspects of studies in liver function; and Dr. Lewis Gregory Cole the x ray of gallbladder lesions.

Other meetings at the academy were those of the Section of Dermatology and Syphilis, on December 1st, when cases were presented from Cornell University Medical College Clinic and from the syphilis clinic of Bellevue Hospital; the Section of Surgery on December 4th, when papers were read by Dr. Howard Lilienthal on Rubber Dam in Abdominal Surgery, and by Dr. Henry H. Ritter on Fracture about the Elbow Joint; the Section of Neurology and Psychiatry made its meeting on December 8th a memorial to Charcot, in cooperation with the New York Neurological Society. Lieutenant Colonel Fielding H. Garrison, of Washington, D. C., gave an interesting talk illustrated with slides and other exhibits on Charcot and the Salpétrière; Dr. M. Allen Starr spoke on the Charcot centennial in Paris; Dr. Charles Loomis Dana read a paper on Charcot and the Arts; and Dr. Bernard Sachs one on Charcot the Hypnotist and Diagnostician. The Section of Pedriatics met on December 10th, when a case of polymyositis was presented by Dr. Sara Welt-Kakels, and papers read by Dr. Bret Ratner, Holmes C. Jackson, Ph.D., Dr. Helen Lee Gruehl, and Dr. Robert A. Cooke. The Section of Otology met on December 11th, when a case of chronic mastoiditis was presented by Dr. Mark J. Gottlieb, and Harry A. Goalwin read a paper on the X Ray Diagnosis of Diseases of the Petrous Pyramid.

* * *

Dr. Vittorio Putti, professor of orthopedic surgery at the University of Bologna, delivered an address on the University of Bologna in the History of Medicine at a joint meeting of the Association of Italian Physicians of America and the Italian Brooklyn Medical Society on the evening of Saturday, December 5th, at the New York Academy of Medicine.

* * *

The ninth lecture in the practical lecture series being offered by the Medical Society of the County of Kings was given on December 4th by Dr. William H. Lohman. His subject was the Management of Pneumonia and Its Complications.

* * *

The Alumni of the Hospital for the Relief of the Ruptured and Crippled, New York City, held their eleventh reunion on November 23d and 24th. In addition to special clinics arranged for the occasion, the program included the following addresses: Recurrent Dislocations of the Shoulder, by Dr. T. Turner Thomas; Pathology of Joint Tuberculosis in Its Early Stages, by Dr. Allen De F. Smith; Cases Illustrating Traumatic Origin of Bone Sarcoma, by Dr. William B. Coley; Critical Comments on Various Types of Stabilizing Operations on Feet, by Dr. Royal Whitman; Use of Lipiodol in the Diagnosis of Obstructive Lesions of the Spinal Cord, by Dr. William Sharpe; A Modified Hey Groves Operation for Reconstruction of the Anterior Crucial Ligament of the Knee, by Dr. Arthur Krida.

* * *

Among prominent visitors in New York during the past few weeks have been Dr. Lorant Hellebranth, of Budapest; Sir Bertram Dawson, physician to the King of England and chief physician to London Hospital; Dr. Kathleen Lynn, of St. Ultan's Baby Hospital in Dublin, Ireland; and Dr. Wilfred M. Post, chief surgeon of the American Hospital in Constantinople.

* * *

Under the auspices of the American Stomatological Association, a series of courses is being offered to licensed physicians and dentists, with a view to better training of the profession in affections of the teeth. The list of courses follows: Stomatological Bacteriology, under the direction of Dr. William H. Park and Dr. Charles Krumwiede; Diagnosis and Focal Infections, Dr. George Reese Satterlee, Dr. Homer E. Smith, Dr. George A. Wyeth, and others; Stomatological Hygiene, Dr. Alfred J. Asgis, and Dr. E. B. Hardisty; Dietetics in Stomatologic Practice, Holmes C. Jackson, Ph.D.; Clinical Dietetics, Dr. Robert H. Rose. Clinical and laboratory courses will be given at Fordham Hospital, University and Bellevue Medical College, Medical Laboratories, Midtown Hospital, and elsewhere. Information may be obtained from the Director of Classes, Aeolian Hall, 33 West Forty-second Street, New York.

* * *

Although as yet no official announcement has been made, it has been widely reported in the European press that an exhaustive investigation of sleeping sickness in Equatorial Africa will be made by the League of Nations in cooperation with prominent medical societies and other scientific organizations and institutions. It is reported that Great Britain has donated more than $15,000 and the use of the

government laboratory at Uganda; that France and Belgium have collectively donated 150,000 francs and Spain 5,000 pesetas for the cause.

* * *

Dr. George B. Eusterman of the Mayo Clinic, Rochester, Minn., held Dr. Ludwig Kast's clinic at the Post-Graduate Hospital, New York, on Friday, December 4th. His subject was Newer Clinical Aspects of Gastric Cancer.

* * *

The Bureau of Clinical Information of the New York Academy of Medicine has on file and for distribution to all interested full information about postgraduate study, not only in New York City, but in foreign institutions. This information will be furnished gladly upon application at headquarters, 17 West Forty-third Street, or by request over the telephone.

* * *

The New York Physicians' Association held a meeting on the evening of Wednesday, November 25th, at the Chemists' Club, New York. Dr. Arthur A. Landsman presented a case of congenital caudal appendage of the sacral region, and the papers of the evening were read by Dr. A. S. Maclaire and Dr. William Sharpe. Their subjects were, respectively, Symptoms and Signs of Proven Acute Cases of Intracranial Hemorrhage in the Newborn, with lantern slides; and Intracranial Hemorrhage in the Newborn, Acute and Chronic Conditions.

* * *

Dr. Horace W. Pike, director of psychiatry at the Danville, Pa., State Hospital for the Insane, delivered a lecture on psychopathic traits in children and their early detection before the convention of the Western New York Teachers on November 20th in Buffalo.

* * *

Dr. Fernando Luz, of Bahia, Brazil, who has been in this country for several months doing postgraduate work, will return to South America on December 15th.

* * *

The Brooklyn Society of Internal Medicine met on November 27th. The program included a case report by Dr. Joshua M. Van Cott, and a paper on Sporadic Paratyphoid Fever by Dr. Luther F. Warren.

* * *

The Clinical Society of the Jewish Memorial Hospital held a regular meeting on December 1st. The speakers included Dr. E. Hoenig, Dr. Mark Hornstein, Dr. Frank Horn, Dr. H. Krauskopf and Dr. J. F. Montague.

* * *

At the recent annual dinner of the British National Institute of Industrial Psychology, the president, the Earl of Balfour, gave an interesting account of the activities of the institute. He characterized its work as a survey of "that vast realm covered by the operation of the factory acts; it is striving to introduce into that realm improvements in mental and bodily conditions of work whtich are within the power of the masters and men to arrange for themselves, and bring into being and put into execution, a study of such things as lighting, heating, ventilation, the movements of the body, cultivation of interest, the avoidance of fatigue, and occupational guidance—in other words, the study of the whole human factor in relation to the machine and the job."

* * *

The American Society of Regional Anesthesia held a meeting on December 1st at the New York Academy of Medicine. The subject of the meeting was Clinical and Experimental Investigations in Spinal Anesthesia, illustrated with lantern slides and hydrostatic apparatus, by Dr. John O. Bower, Dr. George Wagoner, and Dr. J. H. Clark.

* * *

At the meeting of the Dental Hygienists' Association at the New York Academy of Medicine on December 1st, Dr. Alfred J. Asgis addressed the society on the subject of Public Stomatology and Ulotropsis. Dr. Asgis spoke also before the Eastern Dental Society in Philadelphia on Pyorrhea Alveolaris, Dentoalveolar Stomatitis and Ulotropsis, at a meeting on December 3d.

* * *

The New York State Medical Society and the State Department of Health, through the Division of Maternity, Infancy and Child Hygiene, are conducting a postgraduate medical education program consisting of clinics and lecture courses. To meet the increasing demand for these lectures and clinics, according to *Health News*, Dr. Matthias Nicoll, Jr., State Commissioner of Health, has appointed Dr. George Kosmak and Dr. Frederick W. Rice, of New York, as regional consultants in obstetrics, and Dr. William J. Orr, of Buffalo, Dr. Hugh Chaplin, Dr. G. W. Graves, Dr. W. R. May and Dr. Herbert Wilcox of New York, and Arthur W. Benson of Troy, as revional consultants in pediatrics.

* * *

The eleventh conference of the National Committee for the Prevention of Blindness was held at the Russell Sage Foundation Building from November 30th to December 5th. On the first morning an institute for volunteer workers was held. In the afternoon a joint meeting of the American Museum of Safety and the National Committee discussed the subject of eye hazards in industrial occupations. On the following morning the subject for discussion was, How Can the National Committee for the Prevention of Blindness be of the greatest service, first, to state and local organizations for the prevention of blindness; and, second, to state and local organizations for those already blind, and having preventive departments. At a general session in the afternoon, the speakers included Miss Lydia Hayes, secretary of the New Jersey State Association for the Blind; Dr. B. Franklin Royer, medical director of the National Committee; and Mr. Charles Hayes, director of information and publicity of the American Foundation for the Blind. At four o'clock the meeting adjourned to attend a special meeting and demonstration arranged by the Department of Sight Saving Classes of the Board of Education of New York. That evening a dinner was held for the Special Committee on Research Problems in the prevention of blindness at the Pennsylvania Club. On December 2d there was a joint meeting of the Association on Indian Affairs and the National Committee to discuss the campaign against trachoma among the Indians. Afterwards there was a visit to the eye clinic for preschool children at 413 West Forty-sixth Street. On December 3d clinics, classes and local organizations were visited, and in the afternoon the annual meeting of the National Committee for the Prevention of Blindness was held. The chief speaker was Dr. William H. Wilmer, director of the William Holland Wilmer Foundation at Baltimore. This was followed by a dinner at the City Club for the Board of Directors, Advisory Council, and New York State Committee. On December 4th sight saving classes were visited, and round table discussions were held on various subjects of interest. On December 5th the Committee and its guests were invited to attend a demonstration of the latest developments in modern lighting arranged in their honor by the Edison Laboratories of Harrison, N. J.

* * *

Following is the list of names of officers elected at the annual meeting on November 23d of the Medical Society of the County of New York: President, Dr. William P. Healy; first vice-president, Dr. Henry S. Patterson; second vice-president, Dr. John Douglas; secretary, Dr. Daniel S. Dougherty; assistant secretary, Dr. J. Milton Mabbott; treasurer, Dr. James Pedersen; assistant treasurer, Dr. Ten Eyck Elmendorf.

* * *

Dr. Linsley R. Williams, of the National Tuberculosis Association, Henry J. Fisher, of the United Hospital Fund, and George J. Hecht of *Better Times* have been appointed by the New York Welfare Council a committee to consult with the social agencies of New York City to determine whether any of them wish to conduct their work in joint offices, with a view to thus making more efficient their common services.

* * *

As one means of carrying its objects into effect, the Committee on Periodical Health Examination of the Medical Society of the County of New York has undertaken the observation of health examination work being done at the East Harlem Health Centre. . . . This experiment at the Centre offers local physicians a chance to perfect themselves in the performance of health examination along thorough, scientific lines. The Medical Society's committee is present to impart to those desiring to avail themselves of the opportunity the fruits of over two years' research and study in the field. The County Society was largely instrumental in initiating the preventive examination in the East Harlem Health Centre. As soon as the development of a corps of properly trained physicians has been made certain, the society will relinquish its responsibility in health center examinations.—*N. Y. Medical Week.*

Book Reviews

HEART DISEASE

Diseases of the Heart. By Sir James Mackenzie, F.R.S., M.D., F.R.C.P. Fourth Edition: London & New York: Oxford University Press, 1925. Pp. 496.

In this new edition of Mackenzie's classical treatise on heart disease there has been little change in fundamental clinical content. The book has, however, been completely recast and rewritten in the light of the well known concepts of disease which Mackenzie developed in his last years at the St. Andrews Institute for clinical research. Mackenzie's thesis is that hitherto medical research has not gone beyond the stage of recognizing a symptom or a reaction and giving it a name. He believed that the factors concerned in the production of symptoms might be discovered by studying the functions of living cells, and that the most important symptom referable to the heart—cardiac failure—must be studied from the same viewpoint. Much of the new matter in the book is an elaboration of these theories and is philosophical in nature, for it is the chief and avowed aim of the author to demonstrate the inadequacy of the present views. To the reviewer these newer theories are difficult to understand and do not seem to clarify and simplify the subject as much as Mackenzie had hoped, for it is essentially a vitalistic theory that he has adopted.

The most interesting thing in the book is Mackenzie's account of his own fundamental researches on the arrhythmias, and his description of the train of thought that led to so many important discoveries. There are vivid freshness, independence, and untrammeled thought in his writings rarely encountered in a textbook. His continued efforts to probe into the nature of disease, when burdened by advancing years and illness, are the best evidence of the rare power and energy of the man. It is hardly necessary to call attention to the valuable clinical content of the book, based on the author's wide clinical experience, and illuminated by his rare judgment and discrimination.

AN ENCYCLOPEDIC WORK ON TREATMENT

Index of Treatment. By Various Authors. Edited by Robert Hutchison, M.D., F.R.C.P., and James Sherren, C.B.E., F.R.C.S. Ninth Edition, Revised and Enlarged. New York: William Wood & Co., 1925. Pp. 1035.

Although the title would suggest a purely medical book of treatment, a considerable portion of the book is devoted to surgery. This book also has valuable chapters on the physical therapies (electrotherapeutics, heliotherapy, radiotherapeutics, etc.), and also has a chapter on health resorts. The medical and surgical diseases and diseased conditions are all arranged alphabetically, and the book, including the index, comprises 1035 pages.

A book of this character cannot be reviewed; the work is too encyclopedic. That this book, which lies between books on practice and books on surgery and a many volumed medical encyclopedia, fills a want is evidenced by the fact that this is the ninth edition since 1907. That each edition has been an improvement on the one before needs no proof, the list of contributors giving sufficient evidence that the therapeutic advice given is of the best.

An American criticsm would be directed towards many of the prescriptions given, as the American stomach now rebels against bad tasting liquids when active soluble tablets or capsules will act as well or better. Some of the drugs recommended are really obsolete, as zinc oxide by the mouth (page 223), silver nitrate by the mouth for chronic diarrhea in infants, and dilute hydrocyanic acid. A frequent menstruum suggested is chloroform water, which is very disagreeable to the majority of patients.

The ninth edition of this valuable book should meet with success.

MALIGNANCY

Die Klinik der bösartigen Geschwülste. II. Band. Brust- und Bauchorgane, Harn- und männlischer Geschlechtsapparat, Wirbelsäule und Extremitäten. Mit 267 Textabbildungen und 48 farbigen Tafeln. Leipzig: Verlag von S. Hirzel, 1925. Pp. xvi-740.

It has been shown recently that in Germany almost ten per cent. of 86,216 necropsies revealed a cancer; the number of sarcomas was 0.8 per cent. This large series of cases was used to illustrate the differences between clinical and necropsy diagnoses. Five per cent. of the diagnoses were incorrect as to the nature of the disease in cases of external cancer, and 3.26 were incorrect as to the location of the disease, making a total of 8.26 per cent. of false diagnoses. In the cases of cancer of the viscera, 17.35 per cent. were found to be wrong in regard to the nature of the disease and 15.09 per cent. were wrong as regards location, making a total of 32.44 per cent. of faulty diagnoses in the entire necropsy material. The sarcomas showed a wrong diagnosis in 43.23 per cent. of the sarcoma cases. If we consider that only five per cent. of all the fatal cases come to necropsy it is readily seen that the number of actual cancer cases must be still greater. A more intensive study and an earlier diagnosis of cancer cases is therefore necessary.

This, the second, volume is mainly surgical in nature. The diagnosis and surgical treatment are emphasized. F. Krampf and F. Sauerbruch discuss the malignant affections of the bronchi, lungs, pleura, mediastinum (thymus), heart and pericardium, thoracic wall, and the diaphragm. Ed. Rehn is assigned the malignancies of the esophagus. E. Sonntag takes up the malignant tumors of the abdominal walls. O. Kleinschmidt discusses the pathological anatomy, diagnosis, symptomatology, and differential diagnosis of carcinoma of the stomach. E. Payr contributes a most complete treatise on the various types of treatment for gastric cancer (sarcoma) and their indications. V. Schmieden dilates upon the various malignant tumors found in the intestine and the operative measures necessary. P. Clairmont does the same for the rectal conditions. E. Heller discusses the malignant neoplasms of the liver, gallbladder, pancreas and the spleen and the röntgenotherapy of these conditions. H. Kümmell, Sr., gives an excellent presentation of the subject of the malignancies of the kidneys, the renal pelvis, the ureter and the adrenals, while F. Voelcker and H. Boeminghaus discuss those of the

bladder, the urethra, the testicle and epididymis, the prostate, the seminal vesicle and the penis. N. Guleke is assigned the malignancies of the vertebral column. P. Frangenheim discusses the malignancies of the extremities and also the relationship of tumor formation to trauma.

Each chapter is followed by an extensive bibliography, mostly German. The beautiful colored illustrations and plates are the last word in color photography and the authors and publishers deserve commendation for this comprehensive and beautiful work. The contributors are all authorities in their chosen fields.

NORMAL DIET

The Normal Diet. A Simple Statement of the Fundamental Principles of Diet for the Mutual Use of Physicians and Patients. By W. D. Sansum, M.S., M.D. Illustrated. St. Louis: The C. V. Mosby Company, 1925. Pp. 72.

Within the three score and ten pages of this book is crammed all the knowledge of practical import one need have concerning the normal diet.

Sansum's presentation is simple, direct and adequate. The book should be in the library of every physician, of every hospital, and of every student.

INFANT FEEDING

Feeding and the Nutritional Disorders of Infancy and Childhood. By Julius H. Hess, M.D. Illustrated with forty-two Engravings in the Text and one Full Page Colored Plate. Fourth Revised and Enlarged Edition. Philadelphia: F. A. Davis Company, 1925.

This book is now in its fourth edition. There is a new chapter on celiac disease and the chapters on rickets, scurvy, spasmophilia, acidosis and the anemias of infancy have been brought up to date. There have also been revisions in the section on artificial feeding and in the chapter on vomiting, colic and flatulence, constipation and abnormal stools. The volume is illustrated by numerous engravings and one plate in colors.

MANUAL OF LABORATORY MEDICINE

Clinical Laboratory Medicine. By Henry M. Feinblatt, M.D., and Arnold H. Eggerth, A.B., A.M. Illustrated by Two Colored Plates and Eighty-Seven Engravings. New York: William Wood and Company, 1925. Pp. 424.

This book is somewhat of a departure from the usual laboratory manual, with their necessarily more or less stereotyped collection of diagnostic methods, in that it contains also a description of some therapeutic procedures, such as the technic of blood transfusions, the use of convalescent serum in measles, etc. The book is unusually complete, and the laboratory worker, as well as the clinician interested in the laboratory side of medicine, will find it one of the most useful and practical of volumes. It would seem to be almost "fool proof," for instructions are even given as to the kind of bag to be used in taking blood cultures, with a list of the articles which are necessary for a physician to have with him for this procedure. The contents are about as up to date as it is possible to have them, as is evident by the inclusion of the Dick test for susceptibility to scarlet fever, and the discussion of preventive immunization of this disease by scarlet fever toxin.

There is one feature of the mechanical makeup of the book which is annoying to the reader. In the preface the authors state: "It was thought that the references would be of greater value to the reader if they were placed in the body of the text rather than as footnotes." This has been done with the result that the finished product looks like galley proof. On the first half of page 103, to take but a single example, there is an alternate line of text and line of reference, which makes the reading of the subject matter difficult. It is to be hoped that in the second edition of this very useful book the more conventional method of placing the footnotes at the bottom of the page will be returned to.

ROCKEFELLER INSTITUTE STUDIES

Studies from the Rockefeller Institute for Medical Research. Volume LIII. New York: The Rockefeller Institute for Medical Research, 1925. Pp. 617.

This collection of reprints bears testimony to the great variety of research work being done by members of the staff of the Rockefeller Institute. The range of subjects investigated goes from a study of mosaic disease in tobacco and tomato plants to the bacteriology of the intestinal tract of young calves with special reference to the early diarrhea ("scours"). Of especial interest is the paper of Clement C. Chesterman on the use of tryparsamide in sleeping sickness, which indicates the conquest of another disease by the methods of scientific research, which a volume of this kind so aptly illustrates.

PHYSICIANS' VISITING LIST

The Medical Record Visiting List, or Physicians' Diary for 1926. Revised. New York: William Wood & Company, 1925.

This handy little doctor's helper is unusually attractive this year in appearance and make up. The contents consist of a calendar in good print, giving the changes of the moon, and includes the last six months of the year past and the first six of that to come. Rules for estimating the probable duration of pregnancy are outlined. These are followed by a table of approximate equivalents, including temperature, and medical weight and capacity measures, and linear measures. Next an obstetrical calendar is given in the form of an insert. Following is a list of maximum adult doses by the mouth (apothecaries and metric measures), those included in the *United States Pharmacopœia* being starred. Next is a table showing the wide difference in the size of drops of different liquids, and of the same liquid under different conditions. This table was the work of Albert H. Kinsey and was first published in the *American Journal of Pharmacy.* It shows the importance of prescribing *minims* rather than *drops,* in all cases. Then follows a table of drugs such as are used by general practitioners for emergency conditions. Surgical anesthetics and drugs used chiefly in intramuscular and intravenous injections, which require surgical technic, are excluded. Then comes a table of diagnostic hints on contagious diseases, compiled by Dr. William Rittenhouse; then a page of brief statements of useful medical facts for the general practitioner; and a section on emergencies, including an alphabetical list of poisons and their antidotes. Sections on artificial respiration, signs of death, the writing of wills, and a suggested list of signs for doctors precede the blank pages for special memoranda.

The little book has a folding flexible cover, the pages are giltedged, and it is equipped with pencil and holder.

Medicoliterary Notes.

A notable gathering of physicians and their friends took place at the Waldorf Astoria in New York City on the evening of November 23d, when a dinner was given to make public the plans for the building of the Physicians' Home, *Tranquility*. Among the speakers were Dr. Robert T. Morris, president of the home, Dr. George David Stewart, United States Senator Royal S. Copeland, Representative John J. Kindred, Rabbi Israel Goldstein, Don Seitz, and Drs. Wendell Phillips, Frank J. Monaghan, Walter Bowers, Samuel A. Brown, and George J. Ryan, President of the Board of Education. Dr. Morris announced that 168 acres have been acquired through the benefaction of Dr. Stephen V. Mountain at Caneadea, New York, and that more land is to be sought in the vicinity of Poughkeepsie.

* * *

The recent death of Dr. Edward Willard Watson, of Philadelphia, deprived the profession of one of its well known literary members. Dr. Watson was the author of a number of books, including several volumes of verse, among them *Today and Yesterday, Song of the Flying Hours,* and *If Love Were King.*

* * *

Dr. Beatrice Hinkle has an interesting article in the last number of the *Atlantic Monthly* in which she discusses ably from an analytical point of view some of the problems of modern marriage, in an endeavor to explain why so many marriages of today are socalled failures.

* * *

A member of the Faculty of the University of Lille is reported recently to have found a note written by his father in 1855, in which he said: "I express the view that Pasteur (who was a student there at that time) will make a great name in the world of science. . . . I have had fifty years of experience with students, and never have met with so modest and so studious a pupil as Pasteur."

* * *

Efforts being made in France and the Irish Free State to encourage large families would probably have had the approval of the poet, Swinburne, according to the *Manchester Guardian.* Although he remained a bachelor himself, the poet was very proud of the fertility of his family. He took it as a matter for personal pride that one of his ancestresses bore thirty children.

* * *

The foreign press has recently contained reports of an interesting case in surgery—that of a Japanese monk of fifty-two who fought in the Russo-Japanese war twenty-one years ago and was wounded at Port Arthur. Physicians probed for the bullet at the time, but could not find it. A few weeks ago the monk had a sharp pain in his chest, and the bullet was found and removed.

* * *

A new medical school is to be established in the South at Durham, N. C., the site of the new Duke University, recently endowed by Washington Duke. It is the purpose of the Duke University trustees to associate the medical school with a city hospital, to be constructed perhaps around the existing Watts Hospital, the founder of which was formerly a partner of Washington Duke. It has been announced that probably the resources of the new school will not be limited to the present endowment funds provided by the Duke bequests, but may be increased by donations from the Rockefeller Foundation in pursuance of its usual policy of reinforcing institutions already in existence and soundly based.

* * *

The ancient Taureg tomb, recently discovered in the French Sahara, has disclosed besides valuable relics of a very high type of civilization, a prehistoric statuette of white limestone which has been estimated as having belonged to the Stone Age more than fifty thousand years ago. It is a crudely carved figure of a woman, resembling a Venus found in southern France dating from paleolithic times and another from Germany supposed to be of the Neanderthal age.

* * *

The Bibliothèque Nationale at Paris, the largest library in the world, six hundred years old and for two hundred years in its present building, has for the first time in its history installed a lighting system. Because of fire hazards, the authorities have never allowed any kind of lights in the building, but at last, because of the increase of fire prevention devices, a complete system of electric lighting is being put in.

* * *

The *Survey Graphic* for November is devoted to the subject of municipal health. Among the articles it contains are: The Robust City, by Dr. Haven Emerson; Health Work Pays, by Louis I. Dublin, Ph.D.; The Fever Chart of Progress, by Sir Arthur Newsholme; Guardians of Health, by Lewis W. Hine; In and Out of the Health Workshops, by Mary Ross; Public, Private, and Both, by Homer Folks; The T P R of Public Health; What Should a City Do? by Ira V. Hiscock and Philip S. Platt; What You Can Do, by Dr. George T. Palmer; Where Does Your City Stand? a questionnaire prepared by Dr. Palmer; The Nurse, by Katherine Tucker, R. N; The Schoolroom, by C. E. Turner; Fighting Health Officers I Have Met, by Dr. W. A. Evans; Cancer of Ignorance, by Chester H. Rowell, and the City Health Administration, a reading list compiled by Dr. C. E. A. Winslow. In addition to the special articles, this issue of the *Survey Graphic* contains a number of excellent editorials on the subject of city health.

* * *

The *Current History Magazine* for November contains an interesting article by Vilhjalmur Stefansson on conditions in the Arctic regions. He refutes the old theory that the Arctic is a waste land of ice and snow where there can be no life. Although the summer is only six weeks long, daylight lasts for practically twenty-four hours, long enough to enable many plants to attain a rich and sturdy growth. Another erroneous theory, according to Stefansson, is that the effect of the long months of darkness is depressing. This would be the case, he contends, only for the morbid, although he confesses that he himself was much depressed during his first winter there.

* * *

Another article of interest to physicians is that by Joseph Wood Krutch in the *American Mercury* for November, entitled The Strange Case of Poe. Mr. Krutch sums up his conception of Poe's psychological attitude as follows: "The part which he played in life represented his attempt to act out the rôle which he imagined for himself when he created the various dark heroes of his tales, and his ferocious criticism built up his legend of himself as a man cut off from the majority of mankind by great learning, strange passions, and a dark destiny, not inferior but superior to those with whom he made no part. . . . As the realization that he was, as a matter of fact, the victim of irrational and uncontrollable emotions gradually forced itself upon him, he countered it with the pretense that he was, on the contrary, abnormally clear in his mental processes. . . . Finally, he attempted, in *The Philosophy of Composition,* to convince himself that all his previous work had been but the fruit of this same rational faculty, to which he now clung desperately as a proof of his sanity. Thus the process was complete."

* * *

Recent magazine articles on medical subjects include: Aesculapians of Early California, by Dr. George D. Lyman (*Overland Monthly* for October); What Price Babies? by Alida S. Walker (*Pictorial Review* for October); Before Six, by Mary Ross (*Survey* for October 1st); Scarlet Fever, by Dr. Matthias Nicoll, Jr. (*Delineator* for November); White Magic and Black, by John W. Vandercook (*Harper's Magazine* for October); The Best Cure for Nervousness, by Dr. Harvey W. Wiley (*Good Housekeeping* for October); How to Handle Temper Tantrums, by Dr. George K. Pratt (*Designer* for November); Poison Gas for Home Use, by William G. Shepherd (*Collier's* for October 17); Does the Baby See? by Dr. Charles Gilmore Kelley, (*McCall's Magazine* for October); Steps Toward the Conquest of Leprosy, by Dr. James A. Tobey (*Current History* for October); Quackery and Its Psychology, by Dr. James Edgar Swift (*Scribner's Magazine* for October); That Inferiority Feeling in Children, by Dr. George K. Pratt (*Modern Priscilla* for October).

* * *

In our December 2d issue, we noted among recent publications of interest to the medical profession, *The Challenge of Childhood,* by Dr. Ira S. Wile, but through error the publisher was stated as Alfred A. Knopf, instead of Thomas Seltzer.

Abstracts from Current Literature

ENDOCRINOLOGY

Iodine Hyperthyroidism.—Arnold S. Jackson (*American Journal of the Medical Sciences,* August, 1925) asserts that the number of cases of iodine hyperthyroidism has greatly increased as the result of the popular demand for iodine in the treatment of goitre. He reports thirty-eight cases, twenty of which were observed within the last six months; two terminated fatally. This condition has been termed iodine-Basedow in literature and so became confused with exophthalmic goitre.

Iodine should not be distributed promiscuously either in water or salt, but should be administered in exact amounts and under a physician's order. Even minute amounts of iodine are sufficient to initiate symptoms of hyperthyroidism in certain persons with adenomatous goitres. Iodine should be administered with particular care to children with adenomatous goitres; it should never be given to adults with this condition. Every child in the goitre belt between the ages of ten and twenty years should receive small weekly doses of iodine for the prevention or treatment of colloid goitre. Iodine hyperthyroidism is rare in persons under thirty years of age. It develops only in the presence of an adenomatous goitre. The clinical syndrome may be clearly distinguished from that seen in toxic adenoma or exophthalmic goitre. Thrills, bruits and exophthalmos do not occur. If an early diagnosis is made medical treatment may abort the toxic symptoms. Thyroidectomy is indicated when the condition does not yield to medical measures.

The pathological picture is not characteristic. Grossly, the gland has the typical appearance of an adenomatous goitre containing degenerated, cystic, fibrous and calcareous encapsulated nodules. Colloid may be seen in large amounts. The microscopical picture shows acini of variable size, lined with flat, cuboid cells, and filled with colloid. Fetal acini and occasional small areas of hypertrophic cells are found.

Exophthalmic Goitre.—In discussing several cases of exophthalmic goitre in regard to the spontaneous course of the disease and the effect of various types of treatment, Cyrus C. Sturgis (*Medical Clinics of North America,* March, 1925) summarizes the most important facts as follows:

1. A patient may recover from the disease without any treatment other than avoiding heavy work. This recovery may be permanent; in the patient whose history has reported it has persisted for five years.
2. Although temporary recovery may occur in untreated patients, there is a marked tendency for the disease to recur. Each recurrence is likely to result in additional cardiac injury which may lead to the patient's death.
3. Röntgen ray treatment produces results in a small group of these patients which equal surgery. In many, however, it apparently has no effect.
4. Following partial thyroidectomy, all of the symptoms may reappear, after eight years of perfect health.
5. The administration of iodine to these patients is a valuable preoperative measure, as it is followed by a transient drop in the basal metabolism.

The ideal treatment of exophthalmic goitre, that is, the removal of the primary cause, has not been discovered, as we are still in the dark concerning the real changes which are responsible for the excessive or altered function of the thyroid gland. Subtotal thyroidectomy seems to offer the best chances of cure, although even in the most expert hands a second resection of the gland and occasionally a third is necessary. The tendency for an unknown percentage of patients with this disease to recover without treatment does not argue that treatment should be withheld, for, while a remission may intervene, it is characteristic for a series of waves of the disease to appear which may be responsible for the patient's death in a thyroid crisis, or the production of chronic cardiac disease leading to a life of invalidism. The röntgen ray, while it has a low percentage of apparent cures, is useful if the patient cannot be persuaded to undergo surgery, although it should be discarded after a short trial if the improvement is not striking, as experience shows that additional treatment under these circumstances will be of little value. Iodine, in the form of Lugol's solution, is of great assistance, as in doses of five drops three times daily it usually causes a prompt drop in the basal metabolism, which persists for only a relatively brief interval. It is during this remission that surgery can be performed with the greatest margin of safety.

The Inevitable Damage Consequent upon Goitre.—Frederick A. Coller (*Boston Medical and Surgical Journal,* September 17, 1925) says that endemic goitre can be prevented in a large number of cases by supplying the necessary amount of iodine to overcome the deficiency of this substance. It is also undoubtedly true that iodine in proper doses will reduce and perhaps cure many endemic goitres in the early stages when they consist largely of colloid. After the adenoma is well established and grossly in evidence, and after the degenerations have begun to take place, medication is rarely successful in causing its disappearance. After the patient has reached the age of twenty-five iodine therapy has little permanent effect in eradicating the adenomatous elements in the goitre and injudicious use of iodine may precipitate a hyperthyroid reaction. The longer the adenomas are present the greater the chance there is of the appearance of disabling pathological and clinical conditions, so that one can foretell with certainty that an individual with an adenomatous goitre at twenty-five will in all probability at forty-five have demonstrable lesions of the heart, thyroid and mind. The onset of these complications is usually insidious and the fullblown lesion is ordinarily the first thing that brings the patient for treatment.

There can be no field for radiotherapy in the early treatment of the adenoma without symptoms, whatever may be said about its effect on the stage of hyperthyroidism. Any prophylactic treatment would have to extend over a long series of years and no evidence has been advanced that the adenoma can be destroyed by any selective action of the rays. The surgical removal of the adenomatous goitre at a stage before the onset of symptoms is safe and accurate. If one waits for the development of the sequelæ a mortality begins to appear. Before twenty-five operation is usually not indicated except for gross pressure symptoms and it seems wise to give the goitre a chance to stabilize up to this period, assisting it by medication. The rare appearance of complications and the likelihood of recurrence in adolescence makes surgery inadvisable and no harm can be apprehended by waiting. Removal of endemic goitre after twenty-five has a high prophylactic value and should be urged on the patient as soon as a definite diagnosis is established.

Attempted Classification of Thyroid States.—The view expressed in this paper (*Revue Française d'Endocrinologie,* January, 1925) is the conclusion of M. Lucien, J. Parisot, and G. Richard, as given in their forthcoming treatise on thyroid endocrinology. In refusing the commonly accepted belief in hyperfunction or hypofunction as the characteristic of all thyroid pathology, the authors emphasize the objections raised by Gley, that a small remainder of the gland is sufficient to carry on thyroid function, that a minute graft prevents the disturbances caused by extirpation, and that hypersecretion effects the suppression of the destructive mechanism which normally regulates the entrance of the active principle into the circulation. They note further that nitrogen exchange and carbohydrate metabolism are both disordered as well in myxedema and in Basedow's disease, and the same of coagulation and of the edema caused by the trophic action of the thyroid glands on the skin. On these and still other considerations they base the conclusion that Basedow's disease and myxedema are alike forms of dysthyroidism, in the sense that not the amount, but the quality of the secretion is affected.

The difference between socalled hypersecretion and hyposecretion the authors explain by the form of the pathological lesions in a given case. In myxedema there is a mild inflammation of the parenchyma, chiefly in the connective tissue and tending to atrophy. In Basedow's disease the predominating lesion is one of the gland tissue without atrophy. The difference is perhaps one of degree of infection rather than kind; in myxedema suppression or reduction of morphogenetic hormozones, in Basedow's disease excitation of the neurovegetative system rules the clinical picture. It is possible in some instances to observe the coexistence of the two forms in one gland and even the progressive passage

from one to the other. The existence thus of pure and of mixed pathology leads the authors to adopt a classification of thyroid disturbances in three grades: 1, complete myxedema or athyroidism; 2, incomplete insufficiency, and 3, the Basedow syndromes, the last two being forms of dysthyroidism.

Adrenal Syndromes.—N. Pende remarks (*Revue Française d'Endocrinologie,* January, 1925) on the close connection generally recognized between the adrenal glands and the sympathetic nervous system, saying that physiology and clinical experience absolutely confirm the view that makes of those glands a paranervous glandular organ. Their cortex and medulla, he adduces many facts to show, function, not conjointly, but independently. Among cortical functions he includes adipogenesis and stimulation in both sexes of the mammary gland. His enumeration of the symptoms of insufficiency and again of those of normal and of morbid hyperfunction is long and very comprehensive. In speaking of the treatment of medullary hyperadrenalism, he proposes section of the left splanchnic nerve as a means of reducing secretion of adrenalin on the part of both adrenal glands. This operation, he believes, through limiting the amount of adrenalin produced and through the direct production of abdominal vasodilatation, should bring about a hemodynamic condition effective against circulatory hypertension.

Adrenal Syndromes.—N. Pende presented this paper (*Revue Française d'Endocrinologie,* March-April, 1925) at Milan to the Italian Congress of Internal Medicine, October, 1924. The division of adrenal syndromes into cortical and medullary is only measurably possible on account of the close anatomical and functional relation between cortex and medulla. Provisionally the following symptomatic classification will serve:

1. Symptoms of hypoadrenalism, predominatingly cortical in type: cachexia with inhibition of adipogenesis and hypocholesterinemia; pronounced muscular adynamia, psychic adynamia; hypoplastic condition with arrested development of the genital organs in young subjects.

2. Symptoms of hypoadrenalism, predominatingly medullary in type; melanoderma, hypoglycemia, diminished nitrogen metabolism, asthenia and cardiovascular atony, signs of general sympathetic hypotonia.

3. Symptoms of hyperadrenalism predominatingly cortical in type: abundant nutrition and adiposity with muscular and psychic hypersthenia; possible mammary hypertrophy; hypercholesterinemia; precocious dysharmonic hypergenitalism before puberty, with tendency to development of male characteristics in women.

4. Symptoms of hyperadrenalism, predominatingly medullary in type: hypertensive condition; signs of general sympathetic hypertonia; neurogenous hyperglycemia and glycosuria, angiospastic crises, psychic irritability.

Adrenal Syndromes.—C. Piazza (*Revue Française d'Endocrinologie,* March-April, 1925) enumerates the appearance of physiological adrenalinemia; adrenal effects on sympathetic nervous tone; influence of adrenalin on exchange in general and on carbohydrate metabolism in particular; functional relation of the pancreas and adrenal glands; rôle of the adrenals in cholesterinemia; antitoxic effects. The multiplicity of functions attributed to these organs, differing and specific in relation to cortex or medulla, shows them to be glands indispensable to life. By means of adrenalin the medulla modifies the negative effect on arterial pressure and muscular tone exercised by the various endogenous hypotensors. It moderates muscular contractility and controls capillary tonus. The cortex regulates lipoid metabolism, fixing the toxic lipoids and transforming them into inoffensive products.

The Objective Determination of Gonad Failure in the Male.—A. W. Rowe (*Boston Medical and Surgical Journal,* March 12, 1925) says that the clinical picture produced by ablation or depression of the endocrine function of the male gonad is not constant. The variations are probably due largely to the age at which the failure occurs. Eunuchoid states are frequently due to secondary gonad failure, which is a result of some other endocrine dysfunction, notably pituitary. The treatment of such conditions by use of testicular extracts or implants cannot be expected to give good results. Therefore, every patient showing eunuchoid symptoms should be carefully examined for evidences of other endocrine disease before testicular organotherapy is advised. If such treatment is indicated it is best obtained by implantation of human testicular substance.

The treatment of such conditions as senescence, "sex lassitude," dementia precox, epilepsy, or general asthenia, by gonadal extracts, has no logical basis and is not at present justifiable. There is no definite evidence that the use of testicular extract in tablet form has any specific effect in man.

Endocrine therapy of gonad failure in the human male cannot become an established form of treatment until the effect of such failure upon bodily processes has been determined by objective methods, and the value of therapy proven by demonstrating its effects in the same way. At present the conditions for which organotherapy is indicated are limited to the results of castration and certain eunuchoid conditions.

Transitory Congestive Thyroid Enlargement.—Samuel Z. Orgel (*American Journal of Diseases of Children,* January, 1925) concludes that the prognosis in transitory congestive thyroid enlargement does not seem to be unfavorable to life. It is important, however, to regulate the life of the child so that as little strain as possible is placed on the affected tissues. This can be done by cautioning the child not to shout, sing, count aloud, laugh boisterously, lift heavy weights or strain at stool, and especially to refrain from any act that necessitates hyperextension of the head. The mother should be cautioned against allowing the child to learn to play any wind instruments, if the child is musically inclined. Every means should be adopted to lessen the likelihood of the cervical tissues becoming congested. If it has originated as a congenital deficiency, cure is improbable; if however, it has arisen as a result of violent exertion, it may possibly be cured or disappear spontaneously providing the causal strain can be eliminated. If the cause is not removed and the continuous congestion of the vessels continues there is great possibility of the enlargement becoming permanent.

The proper treatment is still problematic. It may consist of some mechanical appliance for preventing the distention and progressive development of the tumor.

Basal Metabolic Rate.—Henry F. Moore (*Lancet,* January 31, 1925) states that the basal metabolic rate should be interpreted in relation to the history, clinical condition, and physical examination of the patient, and that it cannot and should not be evaluated by itself alone. It may be notably increased in fevers, hyperthyroidism (exophthalmic goitre, thyrotoxic adenomata, and some cases of malignant tumor of the thyroid and thyroiditis, overdose of thyroid substance or thyroxin, many cases of severe anemia, many cases of chronic leucemia, after ingestion of food, from muscular work and in some cases of hyperpituitarism. The administration of insulin and suprarenal extract usually causes some increase in the metabolic rate. It may be notably decreased below the normal limits in hypothyroidism, in the clinical conditions myxedema and cretinism, in traumatic shock, and in chronic insanition.

It is in diseases of the thyroid gland that the determination of the basal metabolic rate is of the most value in clinical medicine. From an anlysis of over six thousand thyroid cases by Boothby and Sandiford a basal metabolic rate of over ten per cent above the average normal values of DuBois and Aub was found in ninety-eight per cent of cases of exophthalmic goitre, and only seven per cent were within the limits of fifteen per cent; fifty-six per cent. of cases of thyroid adenomata showed evidences of hyperthyroidism with a basal metabolic rate of more than ten per cent above normal; the vast majority of colloid goitre cases showed a normal rate and a few showed an increase up to twenty per cent above normal. According to other authors, cases which show the "sympathomimetic" symptoms of the exophthalmic goitre syndrome (tachycardia, tremor, exophthalmos, asthenia, diarrhea, sweating) without the increase of the basal metabolic rate and without goitre are to be considered not cases of hyperthyroidism but of "autonomic imbalance." These are called borderline cases by Means.

From a study of their own cases and of the literature, the author concludes that the test gives useful information for estimating the degree of thyroid deficiency, of thyrotoxicosis and the results of treatment, that it gives considerable information in the differential diagnosis of mild and doubtful cases suspected of hyperthyroidism or hypothyroidism, but that it is not of great value in frank cases of hyperthyroidism, myxedema, or cretinism.

Iodine in Exophthalmic Goitre.—Francis R. Fraser (*British Medical Journal,* January 3, 1925) studied the effect of iodine administration in twenty-four cases of exophthalmic goitre. It is reported that iodine can bring about a lowering of the basal metabolic rate and of the heart rate, and an increase of body weight, with a striking improvement in the general condition of the patient. The improvement obtained, however, with the iodine does not as a rule persist.

The optimum dose at the commencement of the treatment appears to be about fifteen minims of a ten per cent. solution in alcohol but this dose cannot as a rule be maintained more than a few days or weeks. If the administration is stopped the condition immediately relapses. For prolonged treatment the dose should be diminished as soon as the initial improvement has taken place, and the administration continued with doses of three to six minims daily. The doses must be carefully regulated according to the condition of the patient. Increasing hardness of the thyroid gland is an indication for smaller doses. The condition of the patient may be made worse, instead of better, if too large a dose is employed.

Iodine in the Treatment of Goitre.—William A. Plummer (*Medical Clinics of North America,* January, 1925) reports that in the Mayo Clinic they now give ten minims of Lugol's solution as a routine three times a day for at least seven days previous to a thyroidectomy. The solution is administered for a longer period to patients who have been in a particularly bad condition, and at the end of this period are rapidly improving. To patients in a crisis or near crisis, fifty minims are given during the first two or three hours, by mouth if it can be retained, otherwise by rectum. If the patient is in a crisis, this is followed by fifty minims during the following forenoon. To the patients having socalled postoperative recurrences that can be controlled are given ten minims of the solution daily over an indefinite period. This period is generally determined by stopping the iodin at the end of ten days. If there is any recurrence of hyperthyroidism, the administration of iodin is again resumed.

The results may be briefly stated as follows: The symptoms characteristic of the disease, as distinguished from the symptoms that might result from the administration of thyroxin, disappear in from one to ten days. This includes the "stare" but not the exophthalmos, which in a sense remains a deformity. The crisis is always controlled within twenty-four hours. As a rule, the patient can take food within a few hours. Since the introduction of the use of iodine the mortality has been rapidly reduced. The operative mortality has been reduced two per cent. or more by the administration of iodine. Preliminary ligations have, to a large extent, been eliminated from the treatment. The surgical mortality, by case, this year is 0.6 per cent.

Iodine Toxicity in Goitre.—E. Ledoux (*Revue de médecine,* November 4, 1924) states that although it is well recognized the paucity of iodine in the food and atmosphere is an important etiological factor in many goitres, the relationship of the amount of iodine in the thyroid gland to the functional state of the latter is still a mooted question. In some cases of dysthyroidism, and even of exophthalmic goitre, determination of the iodine in the thyroid yield figures sufficiently variable to preclude the conclusion that hyperthyroidism is definitely attended with an excess of iodine in this organ. In myxedema with marked loss of colloid substance and hyperplasia of the nonglandular tissue, iodine treatment has no effect, while in goitre with with some remaining colloid and affinity for iodine, the drug causes both general improvement and reduction of the goitre. Rilliet in 1860 recognized in some individuals, upon administration of iodine, a "constitutional iodism" featured by loss of weight, palpitations, dyspnea, sweating, insomnia and extreme nervousness—a condition strikingly similar to Graves's disease. Gauthier asserts that these special forms of iodism may develop alike in persons with latent goitre and those with manifest goitre. Thus, the inhabitants of Geneva, Switzerland, who are more or less predisposed to goitre, are asserted to develop the symptoms of "constitutional iodism" when they visit the iodine laden environment of the seacoasts. In a few cases iodine absorbed by goitre cases has led to an acute thyroiditis with swelling, redness, heat, pain and moderate fever. Much more often, it gives rise to "iodine Basedow," which is the same as Rilliet's "constitutional iodism," and may be so marked as to include tachycardia, premature contractions, tremor, exophthalmos, diarrhea, flushes, copious sweats, and sometimes glycosuria with acetonuria. The pharmacological form and mode of introduction of the iodine exert little influence on these complications. In fact, even the dose itself seems of relatively slight importance, the author having observed cases of iodine Basedow after a few rubbings of iodide ointment over the goitre, while Roth has reported it after ingestion of a few tablets of iodostarin, containing only minute amounts of iodine. As such manifestations are by no means exceptional, caution is in order in the treatment of goitre with iodine and iodides.

Iodine as an Aid to Surgery in the Treatment of Exophthalmic Goitre.—Arnold S. Jackson (*Lancet,* April 11, 1925) found the use of iodine, as advocated by Plummer in the treatment of exophthalmic goitre, to be the most important factor in reducing the operative mortality in his series of cases. The development of a highly perfected operation, with the consequent reduction in time, the fact that patients come to operation at an early stage in the disease, and improved methods of anesthesia, are other factors tending to reduce the operative mortality. Iodine will not permanently cure, but merely temporarily alleviate the symptoms of exophthalmic goitre. The use of iodine will prevent or terminate, however, a fatal crisis as well as postoperative hyperthyroidism. The necessity for ligation is eliminated in ninety per cent. of cases by the use of iodine. Patients are given thirty drops of Lugol's solution daily for three days and forty or fifty drops for one or two days. Following the operation, Lugol's solution is administered by mouth and by proctoclysis. The average stay in the hospital is reduced to five days, as the patients are able to take the preoperative treatment at home. Within forty-eight hours after the ingestion of iodine, there is a marked abatement of all the symptoms of hyperthyroidism. The nervous, vascular, and digestive svstems are all favorably influenced. There is an average reduction of plus nineteen per cent. in the basal metabolic rate.

Goitre Heart.—Nellis B. Foster (*American Journal of the Medical Sciences,* May, 1925) says that cardiac symptoms associated with thyroid disease are of common, even usual occurrence, but these symptoms may be of pronounced severity without detectable evidence of heart disease. The socalled cardiac deaths which follow operation are seldom due to heart failure but more often to vascular failure; that is to say, there is, in these cases, a vasomotor paralysis and a widening of the peripheral vascular field notable by a sharp drop in the diastolic blood pressure, a condition similar to shock.

The commonest type of disorder referable to the heart in thyrotoxicosis is auricular fibrillation. Whether this arrhythmia is due to lesions in the myocardium or to nervous influences is not yet known. Lesions in the myocardium have been described in cases of thyroid disease and they have been experimentally induced in animals, but these lesions are not found in every case. Heart block and auricular flutter are of exceptional occurrence and probably denote serious myocardial degeneration. It is important to control auricular fibrillation, especially if operation be contemplated, since the mortality in cases with fibrillation is higher than in controlled cases. A reversion to normal rhythm may be usually secured by proper treatment, which includes rest, digitalis and quinidine.

Circulatory Disturbance in Diseases of the Glands of Internal Secretion.—Observations by Field and Bock at the Massachusetts Hospital lead J. H. Means to conclude (*Endocrinology,* May-June, 1925) "that if, in the normal person because of the performance of muscular work, or in the patient with Graves's disease because of excess of thyroxin, the tissues call for an increased supply of oxygen, the circulation responds to the demand adequately, that is with an increment apparently somewhere nearly proportional to the increment in demand. The work induced circulation increase of the normal person, however, is brought about by an increase both in pulse rate and amplitude of beat (output per systole), whereas, in that resulting from hyperthyroidism, the increased heart output seems largely to result from increased pulse rate alone, the output per systole showing a less striking tendency to rise." "Metabolic rate increases are accompanied by blood flow increases of varying degrees. In muscular work blood flow just parallels or falls somewhat short of metabolic increase. In hyperthyroidism blood flow parallels or somewhat exceeds metabolism, and after adrenalin injection it very markedly exceeds metabolism. In muscular work and after adrenalin there is an

increase in both rate and amplitude of heart beat, while in hyperthyroidism the increase in rate is the more striking of the two." Probably in the case of adrenalin there is an action directly upon the heart itself, increasing its force of beat, and peripherally there is vasodilatation. The point emphasized is that the signs of hyperthyroidism are understandable on the basis of the known morbid physiology, that is, rapid metabolism and blood flow and a certain amount of arteriolar dilatation, together with the direct cardiac resultants of long continued overwork and hurry and finally fatigue and failure.

The Heart in Exophthalmic Goitre.—A. Oswald (*Schweizerische medizinische Wochenschrift,* January 15, 1925) asserts that the cardiac disturbances in exophthalmic goitre are mainly due to an increased irritability of the nerve supply (extracardial) of the heart, as well as of the intracardiac centres of stimulation (from which the heterotopic stimuli producing the arrhythmias originate). This condition of increased excitability forms part of the general affection of the nervous system. It has been proved experimentally and clinically that the hormone of the thyroid gland increases the lability of the entire nervous system. The thyroid secretion, however, is not a stimulant for the nervous system, *per se,* but only increases its predilection to stimulation. It acts as a sensitizer, and, consequently, even physiological stimuli may produce pathological effects.

The chief factor in the treatment is rest. Hydrotherapeutic measures, such as warm baths and carbonic acid baths, are secondary factors. Cold applications should not be made without due consideration. Dietetic measures are important. Therapeutically, cardiac tonics should be given very cautiously, and digitalis, particularly, is not recommended, as not only is it usually valueless, but it also seems to favor the development of auricular flutter. Ouabain, however, which has an effect similar to that of digitalis upon cardiac activity but is not such a powerful stimulant, is recommended. Eserine, which reduces the irritability of the cardiac fibres, combined possibly with strophanthus, may be used. Quinine may be used successfully in attacks of tachycardia, as it has a negative dromotropic effect. Nervines (baldrian, adonis, crataegus) are especially indicated. In recent times, preparations of ergotoxin have been recommended for their property of paralyzing the sympathetic nerves.

Pathology of Exophthalmic Goitre.—Richard B. Cattell (*Boston Medical and Surgical Journal,* May 21, 1925) thus summarizes his paper:

1. In eighty-seven and nine tenths per cent. of patients with exophthalmic goitre, in our series, receiving iodine therapy, there is an involutional change in the thyroid gland; six and seven tenths per cent showed an increasing hyperplasia.
2. There is an increase in the iodine content of all glands after iodine administration.
3. The iodine content is directly proportional to the involutional change, up to a certain point.
4. Similar changes follow superior pole ligations and hemithyroidectomy together with rest, but it is most marked after iodine alone.
5. The clinical improvement seen after iodine bears a relation to this structural and especially chemical change.
6. There is a group of patients who show marked involutional change and a high iodine content in their glands, yet still suffer from severe exophthalmic goitre.
7. The pathology of exophthalmic goitre is not constant; parenchymatous hyperplasia is seen superimposed on adenomata and endemic goitres.
8. Lymphoid infiltration occurs as the rule; it remains after involution to some degree.

Compensatory Hypertrophy of the Thymus Gland in the Rat.—J. Marmorston-Gottesman and Henry L. Jaffe (*Journal of Experimental Medicine,* September, 1925) by removing one lobe of the thymus of the young rat, studied the enlargement of the remaining lobe. The results indicate that hypertrophy takes place, and emphasize the functional importance of the thymus gland before puberty, since the compensatory enlargement does not occur after puberty. With the onset of involution, there is a marked or almost total decline in the function of the gland, in spite of the fact that anatomically the thymus may persist to old age. With the appearance of a stimulus for regeneration, e.g. suprarenalectomy, the involuted gland takes on functional activity.

Capillary Arches, the Endocrine System, and Feeblemindedness.—The capillary loops of the nail furrows were observed by J. W. Jänsch (*Bericht über den Zweiten Kongress für Heilpädagogik in München*) to be normally very fine and hairlike after the period of infancy, forming a dentated network beneath the edge of the corium. In early infancy these fine capillaries do not exist, but only the horizontal layer of bloodvessels from which they will spring later. The new growth occurs about the sixth month of life. But in a large number of cretins examined the capillaries of the nail furrows were knotted and twisted in irregular formations in those above six months of age. The author regards this as a reliable diagnostic feature of true cretinism, appearing some months after birth in conjunction with other changes in the colloid chemistry of the skin, such as persistence of infantile lanugo, and with ununited epiphyses, persistent bone nuclei, especially in the carpus, stunted growth, psychic deficiencies, and the infantile condition of the bones of the skull and teeth. Under a course of thyroid treatment the capillary condition improved and finally sometimes approached very near the normal regular arrangement. In classes of normal children in the schools of Marburg and Cassel the capillaries of the nail furrows contrasted in the same way with those of children in the school for defectives, and thyroid administration to the latter produced corresponding gradual improvement in this as in mental and other respects. The observations were made with the capillary microscope devised by O. Müller.

Study of Thymus Glands.—Guy L. Bliss (*Archives of Pediatrics,* April, 1925) presents the following summary of his work:

1. Many investigators report that an apparently socalled enlarged thymus, which can be demonstrated by percussion and on the röntgenogram, is very common.
2. The function of the thymus has not been proved. Presumptive evidence classes it with the endocrines.
3. The topography of the thymus lends evidence to the view that part of the symptomatology may be of pressure origin.
4. In the majority of cases a dangerously enlarged thymus presents a definite symptomatology.
5. All apparently socalled enlarged thymus glands do not have symptoms.
6. Socalled enlarged thymus glands without symptoms are not considered dangerous.
7. The norm for thymus gland for a baby of a given size, age and weight has not been established.
8. The cause of thymic death has not been proved.
9. The term "symptom producing thymus" is preferable to "enlarged thymus."
10. Röntgenotherapy is efficient and unattended with danger, but it must be borne in mind that only enough röntgenotherapy should be used to relieve dangerous symptoms, and that in the hands of an expert.

An Extract Obtained from the External Bovine Parathyroid Glands Capable of Inducing Hypercalcemia in Normal and Thyreoparathyroprivic Dogs.—A. M. Hjort, S. C. Robison, and F. H. Tendick (*Journal of Biological Chemistry,* August, 1925) present evidence indicating that the bovine parathyroid glands contain an acid extractable hormone capable of inducing hypercalcemia in dogs. The active substance is probably obtainable from the lipoid free constitutents of the glands, and is rendered soluble in both alcoholic and aqueous acid media although alcohol is in nowise essential. Boiling the finely ground glands is as good if not a better means of extracting the hormone than digestion at room temperature. The hormone is active in increasing the serum calcium of thyroparathyroprivia as well as of normal dogs. The active substance must be quite stable when it is not affected by boiling.

The Internal Secretion of the Ovary and the Tonicity of the Vegetative System.—From the observations of A. Crainicianu it appears (*Presse Médicale,* January 28, 1925) that complete removal of the ovaries lowers the tonus of both the vegetative systems. The absolute tonus of the sympathetic is habitually diminished on extirpation of the ovaries. The absolute tonus of the vagus also declines, but presents oscillations. Sometimes the fall is so considerable that it finally reaches zero. The internal secretion of the ovary in conjunction with that of the other glands maintains the tonus of the vegetative system: consequently, when the secretion is withdrawn, the vegetative tonus is lowered.

PEDIATRICS

An Enlarged Thymus in an Infant; Tetany After X Ray Treatment.—The history given by M. J. Konikow (*Endocrinology,* January-February, 1925) is of an infant in whom dyspnea from birth was caused by thymic enlargement. Tetany occurred at five weeks of age after two x ray treatments to the thymus, and calcium and parathyroid substances were ineffectual in counteracting it. The author believes the x ray treatment responsible for the tetany by impairing the parathyroids as well as the thymus gland.

Treatment of Rectal Prolapse in Children.—Julio Schwarzenburg (*Archivos Americanos de Medicina,* July, 1925) reports four cases of rectal prolapse successfully treated by the method of Schotter and Lembach, namely, the perirectal injection of one to two centimetres of milk in three or four places, making a total amount injected of four to eight centimeters. If the first treatment is unsuccessful the injections may be repeated one or more times at intervals of six or seven days.

X Ray Therapy of Chronic Cough in Children.—Lewis J. Friedman (*Archives of Pediatrics,* March, 1925) reports gratifying results in two cases of chronic cough of varied etiology in children. The more favorable results were observed in treatment of cough following pertussis. The roentgenographic findings in the chest subsequent to treatment revealed little if any change, but the annoying subjective symptoms disappeared. The thymic residue, however, recedes in all cases. The maximum number of treatments required to produce an amelioration of symptoms was two series of treatments. Complete cessation of the cough was seen at the end of six fractional exposures.

Pathology of Fatal Measles.—James Denton (*American Journal of the Medical Sciences,* April, 1925) says that the primary lesions of measles are located in the lower trachea, bronchi, and the contiguous lung. There are three types of lesions in the buccal mucous membrane: Reaction in focal necroses in buccal epithelium; suppurative lesions in and about submucous glands and their ducts; inflammatory lesions of submucous lymph follicles. Koplik's spot is an inflammatory lesion of a submucous gland, the bluish halo about it is due to the collarlike plexus of venules about the duct. The gram negative bacillus found in the lesions appears to have etiological relationship to measles and deserves further investigation.

The Heart in Faucial Diphtheria.—H. M. Marvin (*American Journal of Diseases of Children,* April, 1925) states that a review of the literature concerning the circulatory system in diphtheria appears to indicate: 1, that degeneration of the vagus nerves is of questionable importance; 2, that there is no specific affinity of the diphtheria toxin for the conduction system of the human heart; 3, that toxic myocarditis is present in a large proportion, possibly in all, of the patients who die of circulatory failure; 4, that there may be, in addition to myocarditis, or independent of it, a primary failure of the peripheral circulation which is ascribed to various factors.

Clinical and electrocardiographic observations on ninety patients with faucial diphtheria were studied, and the only abnormalities in the electrocardiograms which seemed to be of significance were the disturbances in auriculoventricular or intraventricular conduction. Sinus arrhythmia occurred invariably in young patients with heart rates below 95 per minute. Auricular and ventricular premature beats, sinoauricular block, and variations in the form of the P wave were noted seldom and appeared to have no significance. No evidence was obtained to indicate that in some patients the heart was primarily injured and in others the peripheral circulation suffered the first and greatest damage. In the patients with circulatory impairment, the picture seemed to be that of myocardial failure.

The signs of myocardial involvement which appeared to be of greatest value were vomiting, hepatic engorgement and a change in the character of the first heart sound. Syncope occurred but once in the series here reported, and gallop rhythm was noted only three times. There was a complaint of abdominal pain in five of the thirteen fatal cases. Necropsy in five cases showed widespread myocarditis. In one case the entire conduction system was profoundly damaged, in one the sinoauricular node alone was affected and in the others the conduction system appeared normal. The vagus nerves were found to be normal in one case.

Acidification of Milk with Vinegar (Acetic Acid) in Infant Feeding.— Berman S. Dunham (*American Journal of Diseases of Children,* February, 1925) states that acetic acid is added to cow's milk to counteract the effect of the buffer substances of the milk on the gastric acidity. The use of this acid in the form of ordinary household vinegar lessened the cost of acidulation, utilized a common and harmless article of the kitchen for this purpose, and made the grocery store the source of supply.

A pint of vinegar milk is made from one ounce (thirty c.c.) of vinegar (from five to six per cent. acetic acid) to fifteen ounces (450 c.c.) of cow's milk. The vinegar milk is given undiluted, except to infants younger than two months who receive four ounces (120 c.c.) of water or gruel in the total daily feeding. Corn syrup diluted with an equal volume of water is added in the amount of one ounce of the diluted syrup to the pint of vinegar milk. The daily amount of the diluted syrup seldom exceeds an ounce and a half, and this is reduced after cereal feedings are begun. The foregoing mixture is well tolerated as a routine food. Disturbances of digestion are a rare occurrence, and can be corrected by a temporary reduction of the sugar and fat elements of the food.

The clinical results of vinegar milk feeding compare favorably with those of other types of acidified milk. The factors of economy, common usage, wide commercial distribution and safety recommend vinegar for the acidifying agent when acidified milk is indicated.

Insulin in Athrepsia.—Nobecourt and M.-M. Levy (*Bulletins et mémoirs de la Société médicale des hôpitaux de Paris,* July 23, 1925) note that in athreptic infants below three or four months of age the caloric requirements per kilogram of body weight are twice those of normal infants of the same age. Furthermore, athreptics always have digestive disturbances which interfere with the exhibition of a sufficient diet. Observation showed that these infants tolerate large amounts of cane sugar, and that the latter may even save life in otherwise seemingly hopeless cases. It differs from proteins and fats in requiring little or no increase of energy expenditure for its utilization. A further useful step is the addition of an agent affording immediate, intensive utilization of the sugar, namely insulin. In an illustrative case described, no improvement had occurred in twenty days under the usual measures, and death seemed inevitable. Upon giving insulin, the lethal trend was arrested and the child began to gain weight. In this infant, aged three months, maternal lactation had failed and the child did not thrive on milk mixtures. Rapid improvement occurred under 700 grams of milk diluted one third with buttermilk, with addition of fifteen per cent. of sugar, together with two subcutaneous injections daily of four clinical units of insulin and ten mils of thirty per cent. glucose solution. As much as fifty grams a day was gained under this régime.

Allergic Manifestations in Infancy and Childhood.—George Piness and Hyman Miller (*Archives of Pediatrics,* September, 1925) report that disturbances of infancy and childhood that have long been known under the term exudative diathesis are manifestations of allergy or protein sensitizations. Individuals in the group manifesting these disturbances are sensitive to ingestion, inhalation, contact, or parenteral injection of certain foreign proteins. The clinical manifestations resulting from the introduction of such proteins is dependent in character, not on their site of entry into the body but on the particular tissue or tissues which may be sensitized. Thus, in one individual, it may be the lining mucous membrane of the respiratory tract resulting in hay fever and asthma, and in another it may be the skin, resulting in urticaria or eczema, even though the offending protein in both instances is ingested and reaches these sensitized tissues not directly but by way of the blood stream. Often overlooked in infancy and childhood are the allergic disturbances of the nose and throat. Seasonal hay fever, although not common, is, however, not characteristic in this period of life and lack of realization of the possibility of a perennial or chronic type of hay fever, from the ingestion of food proteins, leads to the belief that it is often mistaken for some other condition. Removal of tonsils, adenoids and turbinates does not relieve the symptoms. In fact, such removal often means but a regrowth of tissue consequent upon the lymphoid hypertrophy characteristic of protein sensitization. Of interest is the statement that a large percentage of adult sufferers from asthma and hay fever give a history of eczema or socalled frequent colds in childhood.

Medicolegal Notes.

WAIVER OF RIGHT TO CLAIM PHYSICIAN'S TESTIMONY AS PRIVILEGED

The Missouri Supreme Court holds, Weissman v. Wells, 267 S. W. 400, that where a plaintiff in a personal injury case has called physicians to testify to her hysterical malady after the injury, and testified that she had never been afflicted with hysteria before the injury, she waived her right to claim as privileged the testimony of another physician who had treated her for hysteria before the injury.

ANALYTICAL CHEMIST AS EXPERT WITNESS

In an action by an employee for infection in the thumb, requiring amputation, and alleged to have been caused by absorption into the abraised thumb of bronze powder, it was held, Dickey v. Western Tablet Co. (Mo. App.), 267 S. W., 431, that an analytical chemist of long experience, who had studied therapeutic chemistry in a general way, but had never practised medicine, was competent to testify as an expert witness as to the poisonous effect of copper.

MEANING OF "SOUND HEALTH" AND "GOOD HEALTH" IN INSURANCE POLICIES

The Tennessee Supereme Court holds, Metropolitan Life Ins. Co. v. Chappell, 269 S. W. 21, that, as used in insurance policies and applications for insurance, there is no material difference between the term "sound health" and "good health." The court says that the phrase "sound health," when so used, is not to be taken literally. It does not mean perfect health, or imply absolute freedom from bodily infirmity or tendency to disease, but means generally the absence of any vice or disease in the constitution of a serious nature, or that had a direct tendency to shorten life, as contradistinguished from a temporary ailment or indisposition. That one is in "good health," within the meaning of an insurance policy provision, means that he or she has no grave, important or serious disease, and is free from any ailment that seriously affects the general soundness or healthfulness of his or her system.

Where an autopsy showed that an insured person died of Bright's disease thirty days after the issuance of a policy providing that the insurer assumed no liability unless the insured was in sound health at the date of the policy, such evidence showed that the insured was not in sound health at the date of the policy, irrespective of the insured's knowledge or lack of knowledge that she was not in sound health. The court said: "It is the fact of sound health of the insured which determines the liability of the defendant in this character of policies, not apparent health, or his or any one's opinion or belief that he was in sound health."

VALIDITY OF LEASE OF CHARITABLE HOSPITAL

A charitable organization without capital stock, incorporated for the purpose of building and carrying on a hospital for the care of the sick and of training people to nurse the sick, executed a lease of the hospital to one who, though not occupying the technical position of agent, trustee, or director, was one of the members of the organization who had the management of the institution, and the effect of the lease was to vest in him the exclusive control with right to the entire revenue. In these circumstances, the North Carolina Supreme Court held, Fowle Memorial Hospital Co. v. Nicholson, 189 N. Car., 44, 126 S. E., 94, that it was incumbent on him, in a suit to set aside the lease and enjoin his exclusive control of the hospital, to show that the lease was fairly and openly authorized and executed for an adequate consideration, and that its execution was free from undue or controlling influence, oppression, or imposition.

EXPERT EVIDENCE AS TO CAUSE OF BURNS BY ELECTRICITY

In an action for injury to a boy by coming in contact with an uninsulated electric wire, the doctor who attended the boy gave his opinion that his condition came from burns, and that he was burnt by a live wire. He testified that he had very little opportunity for observation of burns by electricity, but had seen a few cases. The North Carolina Supreme Court held, Graham v. Sandhill Power Co., 189 N. Car. 381, that a question as to whether he had an opinion satisfactory to himself as to whether he caught hold of a live wire with one or both hands, and his answer: "I have an opinion. I don't think he grabbed the wire; I think that his hand just barely touched the wire, his right hand," were properly admitted.

PRIVILEGED COMMUNICATIONS—RAILROADS HOSPITAL ASSOCIATION'S PHYSICIAN

The plaintiff in a personal injury case was a member of a railroad hospital association. His dues, together with those of the other employees of the railroad, kept up the hospital, and the physicians and surgeons employed therein were paid by these dues, and were therefor the physicians and surgeons of the employees of the railroad company. The plaintiff agreed with the railroad's claim agent to be examined as to the extent of his injuries so that he could settle with the claim agent. After examination by one of the hospital surgeons, the surgeon was called as a witness to testify for the railroad company as to the nature and extent of the injuries. The Arkansas Supreme Court held, Johnson v. Missouri Pacific, 269 S. W. 67, that the surgeon's testimony as to information obtained on the examination was incompetent as privileged. The plaintiff had it in his mind to be treated by the surgeon as well as examined for settlement, and if he changed his mind as to settling, that would not constitute a waiver of the privilege.

TESTING KNOWLEDGE OF EXPERT WITNESS

The Texas Court of Civil Appeals holds, San Antonio Public Service Co. v. Alexander, 270 S. W. 199, that to test the medical knowledge of an expert witness on disease, it is proper to ask him about his knowledge of proven standards and recognized authorities on the subject under investigation, and in a personal injury case it was proper to read from a text book on nervous diseases and ask the witness whether he agreed or disagreed with the statements therein.

MEDICAL TESTIMONY NECESSARY TO SHOW CONNECTION BETWEEN INJURY AND DISEASE

In an action for personal injuries, where it appeared that seven weeks after the accident plaintiff became sick with lobar pneumonia and was taken to a hospital for treatment, only one doctor testified for plaintiff as to the connection between the injury and the pneumonia, and he refused to say that the injury caused the pneumonia, though testifying that it made plaintiff more susceptible to the disease. The Pennsylvania Supreme Court held McCrosson vs. Philadelphia Rapid Transit Co., 129 Atl. 568, that this testimony did not justify proof regarding the pneumonia, nor the submission of its effect or expense as distinct items of damage, since it wholly failed to show with reasonable certainty that the disease was caused by the injury. "Of course," the court said, "human frailty presents absolute certainty in this class of cases; but, if one having special knowledge on the subject cannot, in conscience, say that in his 'professional opinion the result in question did come from the cause alleged,' there is in fact nothing in the evidence from which a jury, having no such knowledge, could possibly find that it did."

When You Prescribe

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

and your prescription is filled by some cheap, worthless substitute which some druggists buy in bulk, your efforts are defeated and your patient's condition is jeopardized. You owe it to yourself as well as to your patients to make sure that they get

The Original "Gray's"

which has 35 years of faithful service to the medical profession as its guarantee of

1. Highest Quality of Its Ingredients
2. Painstaking Care and Skill in Its Compounding
3. Uniformity and Integrity of Character
4. Maximum Therapeutic Efficiency.

There is only one Gray's Glycerine Tonic Comp. Insure your results and safeguard your patients by writing your prescription as follows—

℞ Grays Glycerine Tonic Comp. (P.F.Co.)

Valentine's Meat-Juice

In **Diarrhoea, Dysentery** and **Cholera Infantum,** in the **Wasting** and **Febrile Diseases** of **Children,** and in the treatment of **Weak Babies,** the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been demonstrated in Hospitals for Children.

VALENTINE'S PREPARATION
NUTRIO PERMIX
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS.-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Diseases of Children.

W. T. Watt, M. D., *Director Imperial Medical College, Tientsin, China:* "In cases of Infantile Diarrhœa, which weakens and debilitates a child rapidly, I have found VALENTINE'S MEAT-JUICE a great stimulant and quick restorative of vitality. Three years ago when an epidemic broke out in Tientsin, I ordered my staff to try your MEAT-JUICE, which justified all expectations, having been satisfactory to patients and physicians alike."

Dr. Calatraveno, *Late Physician of the Children's Hospital, Madrid, Spain:* "I have employed VALENTINE'S MEAT-JUICE most successfully in cases of convalescence from infectious diseases, and it is especially beneficial for children suffering from urinary weakness caused by extreme debility, as in every case it acted remarkably in restoring their strength with notable rapidity."

Physicians are invited to send for brochures containing clinical reports

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

Miscellany.

London Life in the Eighteenth Century.—We are very apt nowadays to deplore the customs and manners of times gone by and to point to the present time and the present generation as inferior to those say of one hundred years or so ago. As a matter of fact, although there are fluctuations in progress, we have advanced greatly in most respects and, perhaps, especially so in sanitation, hygiene and in preventive medicine generally. A book has been written recently by M. Dorothy George published by Kegan Paul, London, in which she tells of the conditions prevailing in Great Britain among the masses under the first two Georges. The health conditions were appalling, deaths exceeding births, the level of London's population being maintained only by rural migration. Three out of four children died before the age of five, and the infants received in workhouses practically all perished. The desertion of children was common and the Foundling Hospital was established through revolt from "the inhuman custom of exposing newly born infants to perish in the streets." From Stuart days it had been the policy to check the alarming growth of London by repression of new building and congestion naturally followed. Personal hygiene had obvious impediments before the advent of cheap cotton clothing which could be easily washed. But contemporaries seem to have been right in their view that one of the most crushing handicaps on public health was "the orgy of spirit drinking, which was at its worst between 1720 and 1751." Distilling was encouraged in the interests of agriculture, and gin was sold everywhere. The lower populace was hopelessly immersed in drunkenness and the first efforts at regulation of the traffic met with resistance that made them a dead letter. The century was half over before better considered legislation got the upper hand of the evil.

Physical Unfitness.—Physical unfitness is a term merely of relative significance, according to Dr. Chester T. Brown, associate medical director of the Prudential Insurance Company of America. A man may not be fit to fight or to undergo the strain of prolonged or strenuous muscular exertion, and yet outlive the warrior or the athlete. If he is normal, he is fit, and it has been the experience of Dr. Brown and other medical authorities concerned with the problems of life underwriting that fitness, physically speaking, is the rule among men under forty.

During the world war, or rather when the United States entered it and put the draft law into effect, there were enough rejections on physical grounds to create the impression that this was a nation of flatfooted men born with a remarkable assortment of bodily defects. But this, Dr. Brown says, was the result of an attempt to apply to vast numbers of recruits for the fighting forces the extra high standards devised for a peace time army which prided itself on the physical excellence of its personnel.

As a matter of fact Americans meet the medical tests devised to support insurance standards based on normal life expectations extremely well. Rejections of applicants for policies have been steadily decreasing in number for approximately fifteen years. They now represent, in the experience of the Prudential at least, only 6.02 per cent. of the total number of applicants compared with almost twice that ten years ago. But the significant feature of this showing, pointed out by Dr. Brown, is that most of those rejected had passed out of youth and attained the age at which physical imperfections and impairments begin to manifest themselves.

There has been an improvement of more than two and a half per cent. since prohibition went into effect, but Dr. Brown was not inclined to attribute much of the credit for it to the Volstead act. "It is more likely the result," he said, "of our greater appreciation of healthy bodies, though it remains true probably that many of us eat too much and are inclined toward excesses in other ways—straining hearts, for example, by too much exertion in competitive sports. If this were not so, there would be fewer rejections of insurance seekers at the age of forty and beyond. It is also attributable in some part to health propaganda by organized bodies devoted to the object of increasing the span of life.

Health Department Lectures on Social Hygiene.—The New York State Department of Health has arranged a series of special lectures to be given throughout the State as a part of its educational work in venereal disease control. These lectures, five in number, are to be delivered by men and women of wide experience and special knowledge in sex education and venereal diseases. The titles and the aims of the lectures are as follows:

Social hygiene education presents to parents, educators, welfare workers and civic organizations the possible methods for directing the sex instinct into constructive channels.

Coaching your boy on life's problems is intended to advise fathers on the problem of sympathetic parental guidance of normal adolescent boys.

The gift of sex, a similar lecture for mothers and daughters, deals with the value of sex in the development of the individual, the community and the human race.

Building for manhood aims to give adolescent boys accurate scientific information regarding the sex impulse and to inspire them with ideals of clean, moral living by appealing to their instincts of loyalty, chivalry, and the love for a square deal.

Building for womanhood is the corresponding lecture for girls. It emphasizes the need of sympathetic guidance and training to enable girls to understand and to adapt themselves to the crucial physical, mental and emotional changes.

The keen interest of various New York communities in sex education and venereal disease prevention is shown by the fact that since 1919 there were given, exclusive of New York city, almost four thousand lectures with an attendance of about half a million persons, and that there were distributed more than three million pamphlets.

A recent announcement states that the urgent need of the lectures may be gleaned from these facts: many cases of syphilis and gonorrhea are contracted innocently; many adolescent youths are infected before they have acquired an effective sense of social responsibility; hundreds of babies are born annually with either active or latent syphilis; venereal diseases may be arrested by modern medical treatment so that the diseased person will be rendered noninfectious; and many cases could have been prevented through education, character training and the inculcation of health habits during and previous to adolescence.

PARATHYRIN

A Solution for Intramuscular or Intravenous Injection Containing the Active Hormones of the Parathyroid Bodies

Parathyrin is used in the treatment of tetany, paralysis agitans, chorea and other conditions associated with a functionally deficient calcium metabolism such as tuberculosis, osteomalacia, varicose and indolent ulcers.

It has also been used experimentally in certain forms of deranged fat metabolism; in conjunction with insulin in coma of diabetic origin, as well as most convulsive states and in cases of diabetes showing acetonuria.

Ordinarily two doses each week are quite sufficient, but in extreme cases the doses of 1 cc may be given daily or on alternate days for several doses.

The same preparation in triple strength is likewise available for the unusual cases, but the single strength solution is supplied on all unspecified orders for Parathyrin.

Box of ½ dozen 1 cc. ampoules..... $2.00
Box of 100, 1 cc. ampoules..... 30.00

PARATHYRIN INCREASES BLOOD CALCIUM

A Typical Example of the Effect of Parathyrin When Administered to Normal Rabbits Kept on a Constant Standard Diet.

Each rabbit received three doses of single strength Parathyrin subcutaneously at three-day intervals, and were bled for the second test three days after receiving the last dose.

Rabbit No.	Blood Calcium Before Treatment	Blood Calcium After Treatment	Increase in Blood Calcium	Percentage Increase
1	19.5 mg.	22.4 mg.	2.9 mg.	14.9%
2	18.0 mg.	22.0 mg.	4.0 mg.	22.0%
3	15.5 mg.	19.1 mg.	3.6 mg.	23.0%
4	17.5 mg.	20.9 mg.	3.4 mg.	19.0%

DYSCHEZIA

Dyschezia due to functional causes is promptly relieved, and normal action of the bowels gradually restored by the systematic use of

AGAROL

The rational composition of this exceptional preparation cannot fail to impress the thoughtful practitioner. Every ingredient fills a definite purpose, and in their composite influence so closely duplicate natural conditions that the bowels act normally without the least griping or other objectionable effect.

The more familiar the practitioner becomes with Agarol, the more he will appreciate its superiority to ordinary laxatives. A trial in some intractable case will tell him why.

AGAROL is the *original* Mineral Oil—Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contra-indications; no oil leakage; no griping or pain; no nausea or gastric disturbances—Not habit forming.

WILLIAM R. WARNER & CO., Inc.
Manufacturing Pharmaceutists since 1856
113-123 WEST 18th STREET NEW YORK CITY

Chile Has a Social Hygiene Law.—The United States Public Health Service states that the Republic of Chile has recently enacted legislation for the control of venereal diseases. The law establishes a Division of Social Hygiene with three departments, namely, education, control, and healing. The various functions of this division are definitely outlined.

The department of education is held responsible for special propaganda, for the study of educational programs, for the creation of social hygiene professorships in the medical schools, institutes, and normal schools, and for suggestions in elementary social hygiene instruction to be included in general public education. This department is also to direct the control and repression of prostitution, watch over the specialists in venereal diseases, exacting from them the certificate of competence the law requires, and to watch over the practices of public and private laboratories in investigations connected with the bacteriological and serological diagnosis of social diseases. One section of the department of control, the office of control of prostitution, has for its function the control and repression of openly established and secretly practiced prostitution. It also watches over the morals of public resorts. The office of professional control, another section in the same department, has control over the exercise of the practice of surgery as relating to social diseases. It exacts special licenses from physicians and laboratories.

The department of healing, through its central pharmacy office, distributes medicines and curative materials to hospitals and clinics. It maintains a manufacturing laboratory for preparations needed by the pharmacies of the service. The same department maintains an office of clinical statistics and an office of medical information. The latter makes available information on medical progress in experimental investigation, diagnosis and treatment of venereal diseases, tuberculosis, alcoholism, physical education, and hygiene of dwellings; also, on progress of the fight against venereal diseases in different towns which distinguish themselves in this field. The formation of libraries and the supplying of magazines indispensable to the service are to be administered by the office of libraries and magazines.

The social hygiene brigades, one for each of the five zones into which the Republic of Chile is divided, have clinics and hospitals for venereal diseases, degenerates, and tuberculous persons. Provision is also made for brigade reformatories to render hospital service for those who have contagious diseases and have refused treatment in compliance with the law. The President of the Republic is authorized to incorporate programs of study in social hygiene into the textbooks of all schools. There is a penalty for private schools failing to provide such instruction.

Women practising prostitution are submitted to medical inspection to verify their pathological condition. Any woman prostitute declared to have a venereal disease is confined to a hospital during the period of contagion. Those resisting treatment are sent to a reformatory. Treatment of venereal diseases is obligatory and provided at public expense, except in chronic cases. These are to be cared for by private physicians or charitable institutions authorized to do such work. A strict system of reporting of venereally diseased by private physicians is inaugurated. Provision is also made for injunction and abatement measures, making it possible to close up as a nuisance any building which the owner allows to be used for purposes of prostitution. Professional or commercial proclamations relating to operations or advertisements of drugs and specifics for curing venereal diseases are not to be accepted for publication in newspapers and magazines, unless endorsed by the Division of Social Hygiene. A medical certificate of good health is required from both men and women before marriage.

Public Health Courses to Be Given at University Summer Schools.—According to *Public Health Reports* (May 29, 1925), an increasing number of universities and colleges of the United States, apparently, are offering courses in various public health subjects at their summer sessions. In some instances an extensive program of courses is presented, including virtually every subject which a health officer or physician might desire.

Columbia University has issued a separate announcement of courses in public health and preventive medicine and medical courses, some of three and some of six weeks' duration—over ninety courses in all. These are offered under the following heads: Public health and preventive medicine, nursing education, physical education, nutrition, courses for social workers, and medical courses.

The University of Michigan also presents a separate announcement of courses in hygiene, public health, and related subjects—a total of approximately ninety courses, covering a wide field of subjects of interest to sanitarians and physicians. In addition to the work at the university in Ann Arbor, three courses are to be given at the laboratory of the Michigan Department of Public Health in Lansing.

The Harvard Medical School announces graduate courses in virtually all branches of medicine and the medical sciences.

The University of Colorado offers approximately twenty courses at Boulder, of general interest to sanitarians, and nine courses at the School of Medicine in Denver, of special interest to both physicians and sanitarians.

Both the University of Iowa and the University of California, which conducted public health summer schools in 1924, again offer attractive courses.

Rutgers University, in cooperation with the New Jersey State Department of Health, presents a unique program of courses for health officers and public health nurses. Lectures will be given on Friday and Saturday of each week. Courses for public health nurses will be offered as a part of a more extensive program. Courses for health officers and sanitary inspectors will be completed during the present summer session.

Among the lecturers giving courses at these various institutions this year are Richard A. Bolt, Hugh Cabot, Michael M. Davis, Haven Emerson, John N. Force, Allan W. Freeman, H. W. Hill, L. L. Lumsden, E. V. McCollum, Richard M. Olin, Earle B. Phelps, M. J. Rosenau, Thomas W. Salmon, Henry C. Sherman, John Sundwall, Philip Van Ingen, Henry M. Vaughan, Frankwood Williams, and Francis Carter Wood.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

G. W. CARNRICK CO.

417-421 Canal Street - - - NEW YORK, N. Y.

The Smallpox Menace in London.—The medical correspondent of the *London Times* stated in its issue for April 28, 1925, that this present year had witnessed a remarkable increase in the weekly notifications of smallpox. So much so indeed that it can fairly be said that the disease has now become endemic in certain districts of the midlands. He presents a chart in which it can be seen how steady has been the rise in the number of notifications since the beginning of 1922. There is, he points out, no guarantee that the increase has reached its highest point; indeed the neglect of vaccination in many areas makes it highly probable that only the beginning has so far been witnessed. The virulence of the disease, too, is stated to be augmenting. Thus we are rapidly approaching the circumstances in which a really serious and deadly outbreak of smallpox may be expected. That this could ever have occurred must have seemed to our grandparents rejoicing in their newfound deliverance from this plague, utterly incredible. It may be, as has been stated recently, that nothing short of a severe visitation of the disease will open the eyes of the nation to the value of the protection afforded by vaccination.

The Prevalence of Cancer.—The most valuable statistical indications of the prevalence of cancer anywhere are the official death rates which are published by cities, states, governments, and insurance companies, says the American Society for the Control of Cancer.

Morbidity reports are not made, for cancer is not a reportable disease. Such knowledge as is wanted of the number of cases which exist anywhere at any time must be had by special inquiry or from estimates based upon the number of deaths which are reported. The deaths give a poor indication of the cases, for there is no fixed relation between the deaths and cases in the various forms of cancer, or of cancer in the different parts of the body. The duration of a case before death varies between a few months and many years. There is nothing approaching uniformity about it. In consequence of these facts, it is not known, even approximately, how many cases of cancer there are in the United States or in any part of it. It would be desirable to have this information, but no reliable estimates can be made.

Experience with Lactic Acid Milk in Infant Feeding.—Morris Gleich (*Archives of Pediatrics,* August, 1924) claims that lactic acid milk in infant feeding is no panacea. It has a valuable place in the armamentarium of the pediatrist. While lactic acid milk can be used routinely with good results, he believes that ninety-five per cent. of babies will gain on any good method of feeding; the other five per cent. require good nursing as well as careful feeding. Considering athreptics as difficult feeders, lactic acid milk is, as experience shows, an excellent means of helping them. It gives them concentrated feedings and by virtue of its acidity enables them to take and digest it more readily than sweet milk. It was also found valuable for the breastfed baby who needs complementary feedings. Lactic acid milk may probably replace protein milk in the severe diarrheas of infancy. By increasing gastric acidity, it may play an important rôle in the prevention and treatment of rickets and tetany.

New Publications Received.

(We shall publish in future full lists of books received, but we acknowledge no obligation to review them all. Nevertheless, so far as space permits, we shall review those in which we think our readers are likely to be interested.)

THE CONSTANT NYMPH. By Margaret Kennedy. Garden City: Doubleday, Page and Company, 1925. Pp. 344.

DUCDAME. By John Cowper Powys. Garden City: Doubleday, Page and Company, 1925. Pp. 458.

SEGELFOSS TOWN. Translated from the Norwegian of Knut Hamsun, by J. S. Scott. New York: Alfred A. Knopf, 1925. Pp. 368.

ANNUAL REPORT OF LIBRARY COMMITTEE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA. For the Year 1924. Pp. 23.

FROM INFANCY TO CHILDHOOD. The Child from Two to Six Years. By Richard M. Smith, M.D. Boston: The Atlantic Monthly Press, 1925. Pp. 105.

EINFUEHRUNG IN DIE PHARMAKOTHERAPIE. Für Mediziner und Natuwissenschaftler. Von Reinhard von den Velden und Paul Wolff. Leipzig: Georg Thieme, 1925. Pp. 200.

COLDS. Cause, Treatment and Prevention. By Russell L. Cecil, M.D. New York and London: D. Appleton and Company, 1925. Pp. 111.

AIDS TO OBSTETRICS. By Samuel Nall. Revised by C. J. Nepean Longridge. Ninth Edition. New York: William Wood and Company, 1925. Pp. 228.

LES DEBUTS DE LA TUBERCULOSE PULMONAIRE. Par le Dr. L. Ribadeau-Dumas. Avec 16 planches hors texte. Paris: Ernest Flammarion, 1925. Pp. 281.

THE LIFE OF SIR WILLIAM OSLER. By Harvey Cushing, M.D. Two volumes, illustrated. Oxford: the Clarendon Press; New York: Oxford University Press, 1925. Pp. 28.

ARZTE UND PATIENTEN WACHT AUF! Erinnerungen und Warnungen eines Alten Arztes aus 35 jähriger Praxis. Von San Rat Dr. Leo Silberstein. Berlin: Ritter, 1925. Pp. 49.

TUMORS AND CANCERS. A Biological Study. By Hastings Gilford, F.R.C.S. With an Introduction by Sir Frederick Keeble, C.B.E., F.R.S. London: Selwyn & Blount, Ltd., 1925. Pp. 703.

DER ELEKTRISCHE UNFALL. Skizziert für Ingenieur und Arzt. Von Prof. Dr. Med. Stefan Jellinek. Mit 25 Textabbildungen. Leipzig und Wien: Franz Deuticke, 1925. Pp. 142.

OCULAR DEFECTS ARISING FROM SKULL INJURIES. Bureau of Workmen's Compensation, Medical Division Bulletin, No. 10. By John S. Somberg, M.D. State of New York, Department of Labor, 1924. Pp. 49.

THE EMOTIONS, MORALITY AND THE BRAIN. By C. v. Monakow of Zurich. Authorized translation by Gertrude Barnes, A.M., and Smith Ely Jelliffe, M.D., Ph.D. Nervous and Mental Disease Monograph Series No. 39. Washington and New York: Nervous and Mental Disease Publishing Company, 1925. Pp. 95.

A COMPANION TO MANUALS OF PRACTICAL ANATOMY. By E. B. Jamieson, M.D. Second Edition: New York: William Wood and Company; Edinburg and London: Henry Frowde and Hodder & Stoughton, 1925. Pp. 558.

DIAGNOSTIK UND THERAPIE DER MAGENKRANKHEITEN. Von Professor Dr. I. Boas. Mit 145 Textabbildungen und 6 Farbigen Tafeln. Leipzig: Georg Thieme, 1925. Pp. 817.

PRACTICE OF GYNECOLOGY. By Henry Jellett, M.D., F.R.C.P.I. Fifth Edition, with 417 Illustrations (many in color) and 15 colored plates. Philadelphia: Lea & Febiger, 1925. Pp. 744.

CASE OF OSSEOUS METASTASIS FROM PRIMARY CARCINOMA OF THE RIGHT MAMMA. By Sir George Thomas Beatson, M.D. (Edin.), K.C.B. Issued by Research Department of the Glasgow Royal Cancer Hospital. Briston: John Wright & Sons, Ltd., 1925. Pp. 486.

When You Prescribe

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

and your prescription is filled by some cheap, worthless substitute which some druggists buy in bulk, your efforts are defeated and your patient's condition is jeopardized. You owe it to yourself as well as to your patients to make sure that they get

The Original "Gray's"

which has 35 years of faithful service to the medical profession as its guarantee of

1. Highest Quality of Its Ingredients
2. Painstaking Care and Skill in Its Compounding
3. Uniformity and Integrity of Character
4. Maximum Therapeutic Efficiency.

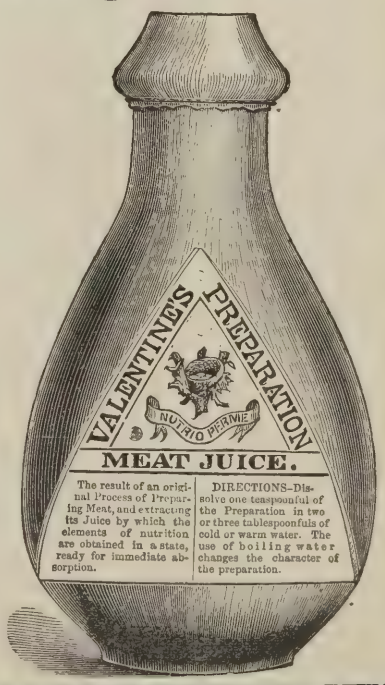
Valentine's Meat-Juice

In **Typhoid, Gastric** and **Other Fevers,** where it is **Essential** to **Sustain** the **Patient** without **Irritating** the **Weakened Digestive Organs, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** of **Restoring** and **Strengthening** when **Other Food Fails.**



VALENTINE'S
PREPARATION
NUTRIO PERAMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

J. R. Wood, M. D., *Physician Sheltering Arms Hospital, Paint Creek, W. Va., U. S. A.:* "I have been using VALENTINE'S MEAT-JUICE in the treatment of Typhoid Fever cases in the Sheltering Arms Hospital, for the last two or three weeks, with the most gratifying results both to the patient and physician. I consider it the best preparation of animal food I have ever seen, in fact, the only one I have ever had any success with."

Dr. Genevaix, *Assistant Surgeon-Major, First Class, Hotel Dieu, Creusot, France:* "The patients to whom I have given the excellent preparation, VALENTINE'S MEAT-JUICE, have found their general condition rapidly improved by it, and in the convalescence from continued Fever (Typhoid and Para-Typhoid) it gives the best results."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
Richmond, Virginia, U. S. A.

S 193

Miscellany.

Huxley.—Thomas Henry Huxley was born at Ealing on May 4, 1825, and when he died at Eastbourne on June 29, 1895, he had been for twenty or thirty years about the best known scientific man in England. With his many fundamental discoveries in zoology and with his many distinctions in other fields, the fact that he was a qualified medical man had little to do. The profession may, however, pride itself on the memory that almost the only regular teaching he ever received was as a medical student at Charing Cross Hospital—a memory revived annually in the Huxley Memorial Lecture—and that it was an appointment as a ship's surgeon in the navy which gave him his practical start in life and the chance of exploring the wonders of the ocean, which he did to such good effect that he was elected a Fellow of the Royal Society at the age of 25 and received a Royal Medal in the following year; in 1881 he became president.

Huxley was in the first place a distinguished comparative anatomist with a bent for philosophical generalization, and at the same time a horror of letting his imagination run in front of the facts of structure which were before him. For twenty-five years he worked in that doubting period of biological thought when, among Lyell and Scrope's uniformitarianism, Cuvier's archetypes, Oken's idealism, and the accurate examination of structure by Johannes Muller and his companions, the world was groping its way to the realisation of the broad truth which Darwin drove home in the "Origin of Species." And in the cumulative development of knowledge which led up to the revolution of 1859 Huxley played a prominent part with such contributions as his recognition and delimitation of the Hydrozoa as a natural group and his work on the theory of the vertebrate skull. Once Darwin had provided a mechanical conception of how evolution worked, Huxley was persuaded where the philosophy of Lamarck and Herbert Spencer had failed to convince him. He became one of the most active protagonists of the new doctrine, and his own work, now largely paleontological, centred round it. In the second place Huxley was for thirty-one years an inspiring professor of natural history at the Royal School of Mines, and when he got facilities at South Kensington in the early seventies he introduced the method of practical class-teaching with types of animals and plants which has been everywhere imitated with such success. As a memorial it would have been appropriate if the "Huxley and Martin" of those early days had not been replaced so largely by the almost equivalent "Marshall and Hurst." And, in the third place, Huxley was a good citizen who felt it laid upon him to rebuke error and propagate truth, and the last third of his life was mostly occupied with his public duties. It is in some ways a little unfortunate that the general public knows him best by his controversial activities. He had a hatred of dogma and privilege and pretense which seems now rather over-fierce, and it is hard for us to be enthusiastic over his polemics with Mr. Gladstone and the Duke of Argyll about the literal truth of Genesis. He hit harder than is customary nowadays, and when he said that you could always remember which side of the heart the mitral valve was on by reminding yourself that bishops were never in the right, he had perhaps forgotten that his first paper to the Royal Society was communicated by the Bishop of Norwich. But our very difficulty in fully sympathizing with his position simply means that he and his fellow workers in the cause of freedom of thought succeeded, and it is in large part their work which has led to the broadminded toleration which makes such controversies impossible in this country—though not in America—at the present day. There was a time when Huxley's name could hardly be mentioned in genteel society; he was a declared agnostic and perhaps he declared it rather loudly. But in calmer days it is not difficult to see peeping out of his writings a rather wistful longing that the intellectual discipline which he had imposed on himself would let him believe a few things which he could not prove. "To do justly and to love mercy and to walk humbly with thy God" was his epitome of an ideal religion. (*Lancet,* May 9, 1925).

Sunlight and Mental Development.—Sir Henry Gauvain is of opinion that the intellectual output is definitely increased as a consequence of exposure to sunlight carried out in a rational and instructed way. The intelligence of a group of children treated by insolation at Alton is higher than that of a similar group under treatment in London, and the difference is apart from heredity or physical condition. We seem to have heard of this before, says the *Medical Press,* June 10, 1925, and the idea gains force when we read that sunlight raises the spirits of those who come under its influence, and renders them more capable of benefiting by the education provided. On the other hand, it is clear that the lack of sunlight may reduce the capability of benefit; but to claim that brain power is dependent upon sunlight is quite another matter. What proof is there that those who inhabit sunny lands have a greater brain development? Doubtless a fine sunlit day exercises an invigorating effect upon the temperament of those who are unaccustomed to that environment. Under similar conditions long-continued, the invigoration becomes lassitude. That is the evidence of the tropics.

New Cure for Pellagra Announced by Government.—The United States Public Health Service has announced the results of experiments which prove that severe cases of human pellagra can be either prevented or cured by means of dried yeast. Surgeons Joseph Goldberger, G. A. Wheeler, and W. F. Tanner, after the successful treatment of twenty-five out of twenty-six patients, have united in a report which reveals that they were led to this discovery by following another disease in dogs. Black tongue, a bacterial disease with somewhat similar effects on the skin as are produced in severe cases of pellagra, also a bacterial infection, was produced experimentally in dogs. Then the dried yeast was given. The cures were so satisfactory in the cases of the dog disease that the Public Health Service surgeons tried the yeast treatment on pellagra patients. As early as the second or third day beneficial results were noted. It is only in severe cases of pellagra that such dried yeast treatment is necessary as in milder cases careful feeding is sufficient.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Post-Operative Constipation

often causes extreme suffering and jeopardizes the efforts of the most skillful surgeon. The anesthetic, the shock of the operation, and in many instances the use of drastic cathartics before the operation, often produce almost complete paralysis of the bowel muscles. Peristalsis ceases and the fecal retention that follows, with the incidental formation of gas, invariably gives rise to severe pain and distress.

To avoid post-operative paresis and gas formation, AGAROL COMP. has been found invaluable. Given regularly a few days or a week previous to an operation, and its administration resumed as soon thereafter as circumstances permit, it may be confidently relied upon not only to produce evacuations without pain or distress, but to prevent the bowel sequelae and complications of surgical operations as no other remedy can.

REMEMBER—Agarol is the original Mineral Oil—Agar-Agar Emulsion, and is perfectly stable, odorless and palatable.

A liberal supply for testing AGAROL will be sent on request

The Common Ground of Law and Medicine.—Lord Justice Atkin was the speaker at the annual meeting—the 151st—of the Middlesex Hospital Medical Society on May 12th, and explored what he called "the dusty purlieus of a lawyer's mind" on the subject of law and medicine. Touching lightly on the history of the two professions, he remarked on the early embodiment of sanitary measures in legal codes, and said that perhaps the most powerful legislators of history had been Moses, Mahomet (both of whom were sanitarians), and the chief medical officer of the Ministry of Health. The professions had proceeded together, but not always at the same pace. While it might be said that the law had exhibited a fairly constant development from later Roman times, medicine had stood still for many centuries after Galen, and, indeed, until about fifty years ago medicine remained more or less an empirical art based upon incomplete experience and upon hypotheses which were to a large extent untrue.

In recent times medicine had made enormous advances and had become a science, which could hardly yet be said of law, for law was subject to variation at the instance of legislatures as well as to the fallible interpretations of judges. Medicine and law were working towards the analogous goals of health and justice, which had much in common. Both professions sought after truth, and both tested carefully the evidence presented to them—lawyers by a process of crossexamination, medical men by ever closer and more accurate observation assisted by elaborate instruments. Crossexamination was rather repugnant to the popular mind because it represented the application of well known and tested principles by which the ordinary man was not guided in his own particular judgments and affairs; instead of relying on what was ascertained by accurate observation, the ordinary man was guided largely by emotional preferences, prejudices, and impressions which had persisted from his youth in spite of evidence that they were erroneously based. Lord Justice Atkin believed crossexamination, properly applied, to be the most effective means of ascertaining the truth whether as to a fact or a theory. In some branches of medicine—psycho-analysis, for example—crossexamination was one of the principal arts, pursued, he did not doubt, at times with great success. That it was an art which required cultivation and practice was illustrated in the courts when some litigant conducted his own case, and failed miserably in his attempts at crossexamining the other side.

The Lord Justice went on to speak of the various ways in which the two professions could assist one another, and the great range of subjects, relating to both civil and criminal law, in which the law depended upon the information given by the medical man. In civil law these subjects included such large matters as marriage, injuries, insurance, and workmen's compensation. The general attitude of the law towards the medical man was to treat him, not as an advocate or as one supporting a particular thesis for its own sake, but as himself a minister of justice anxious to assist the court at arriving at a true conclusion. To doctors who were called upon to give evidence he would say that it was of first importance for them to make sure whether they were speaking of something which they had ascertained as a fact or were simply putting before the court their impression or theory. Many topics of interest to both professions, he continued, were still outstanding. The most important was the great question of insanity and the responsibility of the insane person for criminal acts. Medical men had not yet been able to define what they meant by insanity. The difficulty was as old as Hamlet, and the speaker was not sure that the definition of "true madness"—"nothing else but mad"—had advanced much further. But he hoped that at any rate in respect to criminal responsibility it would be considered a fair and proper thing to find irresponsibility when the crime was committed from irresistible impulse the result of a diseased mind, and he was himself awaiting the time when some legal authority would explain what the true position was in quite well authenticated cases. Another outstanding question was professional secrecy. The extreme claim for privilege probably could not be upheld. There was no protection for a medical man in respect of such matters, and the law would so remain, he had no doubt, until some doctor—might he say, some fanatical doctor?—in the witness box declared that the confidence existing between himself and his patient was as sacred to him as that between priest and penitent or lawyer and client, and that he was prepared to go to prison for the rest of his life rather than violate it. The question would then arise whether the conflicting claims could not be reconciled by something less than a complete obligation on the part of the doctor to make a disclosure when called upon.

The lecturer also mentioned another question, which he said was too controversial to enlarge upon—the question whether medical men might not fairly claim to have decisions affecting professional conduct made subject to some judicial investigation, instead of being left to the decision of any tribunal which did not act upon legal principles and upon evidence which could be tested and controverted by cross-examination. That was a matter he must leave to the doctors. In conclusion, he declared that law, equally with medicine, had important preventive aspects. He was surprised and pained when, at an important medical dinner two years ago, the remark of the Lord Chief Justice that the ideal and practice of lawyers was to be peacemakers was received with derision. Lord Hewart's remark was perfectly true, however much opposed it might be to the "picture-house" view of the lawyer. Each profession had much to learn from the other, and each depended in a large measure on the other's confidence and goodwill. (*British Medical Journal,* May 16, 1925).

Most Child Poisonings Due to Strychnine.—Of seventy deaths due to accidental poisoning during 1924 among children between the ages of one and four years insured in the industrial department of the Metropolitan Life Insurance Co., twenty-four were due to strychnine. This was four times as many as the number due to lye and other alkalies, which came second in numerical importance. Cathartic pills, containing strychnine and left within the reach of children, were one of the most important sources of poisoning it was said.

Studies and Demonstrations in Malaria Control.—In reviewing the activities of the Rockefeller Foundation during 1924, Dr. George E. Vincent, president of the foundation, made reference to the studies and demonstrations made in malaria control during the period under review. He said: "Malaria is a more difficult disease to control than yellow fever. The malaria parasites continue to live in people's blood unless destroyed by the persistent use of quinine in sufficient quantities over a period of several years. Then, too, the malaria mosquitoes are of several closely related species and, unlike the highly domesticated yellow fever insect, breed in natural collections of water, ponds, reservoirs, and ditches, often at a distance from human habitation. Thus malaria control is by no means technically easy, except in the most favorable circumstances, and may not be economically feasible. In extreme cases malaria may and does make whole regions practically uninhabitable. In many parts of the world, for example, in large areas of the tropics, along the Italian coasts, in Macedonia and Greece, malaria is a dangerous, even deadly, foe. Several British colonies, the Panama Canal Administration, the Italian Government, and the United States Public Health Service, among others, have demonstrated the possibility of effecting varying degrees of control by large and small scale drainage, the oiling or Paris-greening of pools, the use of fish, the administration of quinine, the screening of houses, etc.

"Since 1916 the International Health Board has contributed to demonstrations in malaria control, especially in towns and in counties which include urban and rural districts. During 1924 the Board aided thirteen states, twenty-three counties, and one town in the United States and maintained demonstration units in four Brazilian villages near Rio de Janeiro. In three of these latter places the decline in the number of cases was marked."

Crude Rates of Mortality from Cancer.—It has long been puzzling to observe the differences which are reported by different countries. Notwithstanding the fact that all civilized nations are supposed to employ the same system of classifying the data, the rates are curiously unlike. The question has persistently been asked, "Are there really so many more fatal cases of cancer in some countries than in others, or may the differences which appear be ascribed partly to the methods which are employed in observing and recording the deaths?"

No final answer has been made to this question. The weight of the evidence which is now available is that there are real and substantial differences. Similarly, on comparing cancer mortality statistics for the same areas of country over a period of years, there generally appears to be an increase. That cancer is increasing in the United States is the opinion of the government officers who have charge of compiling the statistics. That it is becoming more prevalent in England and Wales is the opinion of the Registrar-General of those countries.

In the United States the figures published by the Census Bureau indicate that there is more cancer in the eastern and far western states than in the middle and southern states. In Europe southern countries seem to have less than northern ones.

Miscellany.

South Carolina Has Effective System of Disease Reporting.—Dr. James A. Hayne, State Health Officer of South Carolina and Collaborating Epidemiologist of the United States Public Health Service, has instituted a new and decidedly more effective system of disease reporting by physicians. Each week a card is mailed to physicians for the report of the number of cases of diphtheria, gonorrhea, syphilis, malaria, smallpox, tuberculosis, and certain other diseases. The greater effectiveness of this system of reporting is shown by the fact that in the first month of its operation 734 cases of syphilis were reported as against an average of 245 cases for each of the preceding ten months, or three times as many cases as were reported formerly. There is a still higher rate of increase in the number of reported cases of gonorrhea. Over seven times as many cases of this disease were reported under the new system as were reported formerly.

Smoldering Fires of Yellow Fever.—In a review of the work of the Rockefeller Foundation for the year 1924, by Dr. George E. Vincent, president of the Foundation, the yellow fever situation is commented upon, as follows:

An outbreak of yellow fever in Salvador (seventy-five cases with twenty-two deaths) in the summer of 1924 was an unanticipated episode in a campaign which began in 1918 under the leadership of General Gorgas as head of a commission of the International Health Board. Control work had been carried on in Mexico and Central America, Ecuador, Peru, Colombia, Venezuela, and Brazil, with a reconnaissance on the Gold and Ivory Coasts of West Africa. No case of the fever had been reported from Central America since 1921. It was hoped and believed that with the possible exception of a small focus of infection in Colombia the disease had been eliminated from the entire area which lies between the Rio Grande and the northern boundary of Brazil. This epidemic, however, taught its lessons. It showed the value of keeping a mobile staff of experts on call. Doctors on duty at other points were instructed by cable to go at once to Salvador to help the Government bring the outbreak under control. The promptness with which this was done proved that international organization against disease can be speedy and effective.

The unexpected flareup in Salvador had another result. It forced a careful review of the theory and practice of antiyellow fever work. How was this outbreak to be explained? Had the infection been brought in from outside or had the previous campaign failed to extinguish the fire completely and left embers smoldering? No absolute answer can be given, but there is reason to think that there may be more than was originally supposed of those endemic areas, i. e., cities, towns, or even clusters of villages between which people are constantly passing to and fro and in which the fever is always present. Guayaquil, in Ecuador, which was freed from the disease in 1919, had long been a conspicuous endemic centre from which the fever was distributed by land routes and by ships. Even if the control of mosquito breeding is neglected yellow fever will disappear provided nonimmune persons do not come in from the outside to keep the infection going. But in settled human groups babies are arriving constantly and growing into boys and girls who are susceptible. Children usually have the disease in a mild form; very often it is not even recognized for what it is. Yet from these sick children mosquitoes may become as dangerously infective as from the severest cases. So it may happen that in a large city or a series of small towns the fever is kept alive without anyone realizing it until adult, nonimmune strangers begin coming in. Then smoldering embers leap into flame. A vigilant watch is being kept against such possibilities. The surveys made in Mexico, Guatemala, British Honduras, Nicaragua, Honduras, Colombia, and the Guianas failed to reveal any cases of yellow fever.

The Hookworm as Advance Agent of Health.—In contrast with yellow fever and malaria, hookworm disease is a simple malady, says Dr. George E. Vincent, president of the Rockefeller Foundation, in his review of the work of the foundation for the year 1924. The process by which tiny worms hatched in a warm and moist soil make their way through the skin of a human host and finally come to rest in the small intestine is well understood and can be clearly explained even to the most ignorant. The vermifuges which expel the parasites are simple and cheap. The building and use of sanitary latrines put a stop to the pollution of the soil and protect the population against reinfection. To weaken the hold and bring under control a disease which robs of vitality, stunts, cripples, handicaps, and even kills millions throughout the hot and moist regions of the world is vitally important in itself. The International Health Board is an outgrowth of the original Rockefeller Sanitary Commission which was organized in 1909 to combat the disease in the Southern States. Since then the campaign has been extended to fifty-two countries in six continents and twenty-nine islands of the seas.

But the control of hookworm disease does more than give relief from one malady. It is an object lesson in public health. It shows a community what organized, concerted effort under trained leadership can accomplish. It is in a real sense an advance agent of preventive medicine, an educator of the public. The board has purposely cooperated in the control of hookworm disease as a way of helping local and central governments to establish or extend their general health organizations. Thus in the United States, Brazil, Australia, and elsewhere hookworm units as such have been merged in regular health services.

Elsewhere hookworm measures are continued. In 1924 the board assisted twenty-four states and countries from the West Indias to Siam, Java, and Ceylon to control the disease, and in eight countries made surveys to find out the extent of the hookworm problem. As usual, government appropriations were increased while the board's share diminished. Simple as hookworm disease seems, much is still to be learned about soil pollution, drugs, various effects of the disease according to age, sex, race, etc. So research went on in the Southern States of the United States and in other countries, notably China.

PARATHYRIN

A Solution for Intramuscular or Intravenous Injection Containing the Active Hormones of the Parathyroid Bodies

Parathyrin is used in the treatment of tetany, paralysis agitans, chorea and other conditions associated with a functionally deficient calcium metabolism such as tuberculosis, osteomalacia, varicose and indolent ulcers.

It has also been used experimentally in certain forms of deranged fat metabolism; in conjunction with insulin in coma of diabetic origin, as well as most convulsive states and in cases of diabetes showing acetonuria.

Ordinarily two doses each week are quite sufficient, but in extreme cases the doses of 1 cc may be given daily or on alternate days for several doses.

The same preparation in triple strength is likewise available for the unusual cases, but the single strength solution is supplied on all unspecified orders for Parathyrin.

Box of ½ dozen 1 cc. ampoules..... $2.00
Box of 100, 1 cc. ampoules..... 30.00

PARATHYRIN INCREASES BLOOD CALCIUM

A Typical Example of the Effect of Parathyrin When Administered to Normal Rabbits Kept on a Constant Standard Diet.

Each rabbit received three doses of single strength Parathyrin subcutaneously at three-day intervals, and were bled for the second test three days after receiving the last dose.

Rabbit No.	Blood Calcium Before Treatment	Blood Calcium After Treatment	Increase in Blood Calcium	Percentage Increase
1	19.5 mg.	22.4 mg.	2.9 mg.	14.9%
2	18.0 mg.	22.0 mg.	4.0 mg.	22.0%
3	15.5 mg.	19.1 mg.	3.6 mg.	23.0%
4	17.5 mg.	20.9 mg.	3.4 mg.	19.0%

SWAN-MYERS COMPANY, INDIANAPOLIS, INDIANA, U. S. A.
Pharmaceutical and Biological Laboratories

Restores Natural Bowel Action

Among the many remedies for constipation, bowel torpor, intestinal stasis or any form of dyschezia of functional origin, there is hardly one that has met with such instant approbation and acceptance by discriminating physicians as

AGAROL

A reasonable test of this scientifically balanced combination of pure mineral oil, agar-agar and phenolphthalein in some severe case of constipation will enable the practitioner to understand why Agarol is winning the regard and confidence of a constantly increasing number of medical men. He will find that Agarol

1st—*produces* prompt and satisfying bowel evacuations;
2nd—*increases* the bulk, softness and plasticity of the fecal mass;
3rd—*imparts* functional tone and power to the intestinal muscles;
4th—*restores* functional activity of the bowels so that satisfactory evacuations will follow regularly and continue without the need of further medication.

Agarol is not only a palliative of intestinal torpor—it is a true bowel corrective.

Child Welfare Legislation.—Current child welfare legislation in the states is summarized in a statement issued recently by the Children's Bureau of the United States Department of Labor. A decrease in the amount and importance of such legislation introduced in the forty-two state legislatures meeting this year compared with 1923, the preceding important legislative year, is noted by the bureau. Information received by the bureau from the states is not complete, however, so that no final conclusions are drawn.

The Children's Bureau review may be summarized as follows:

Child Welfare or Children's Code Commissions.—A children's law commission was created by Rhode Island; the Pennsylvania and Delaware commissions have been continued for two more years; the Utah commission has been discontinued; the New York State commission was discontinued but sponsored 15 bills, seven of which were enacted. The South Dakota commission introduced ten bills, four of which passed in amended form. The Georgia legislature, which is still in session, is considering eight bills drafted by the Georgia children's code commission.

Maternity and Infancy Act.—This act was accepted for the first time by Rhode Island, Vermont, and Hawaii during 1925; forty-three states and Hawaii are now cooperating under the act.

Child Labor.—The child labor amendment was ratified by California, Arizona, and Wisconsin and the House of Representatives of New Mexico and of Montana voted in favor of ratification. Arkansas had ratified in 1924. Both houses in eighteen States rejected the amendment during 1925 (two others in 1924); one house in each of seven other states rejected it (one other in 1924). Authoritative information from other states has not yet been obtained.

State laws relating to the employment of children are known to have been enacted in only nine states—California, Massachusetts, New Mexico, New York, Ohio, Tennessee, Texas, Wisconsin, and Wyoming. In New Hampshire, North Carolina, New York, Rhode Island, and Wyoming, bills to raise the standards of state child labor laws were rejected.

School Attendance.—Laws relating to school attendance were enacted by Massachusetts, Ohio, and Pennsylvania. A bill which would have improved the compulsory school attendance law of South Carolina was reported as defeated.

Child Hygiene.—Measures relating to public health and child hygiene have been considered in a number of states. Bills authorizing the employment of public health nurses by municipalities and counties were passed in Kansas, Michigan, and Missouri. A Connecticut bill would provide for state aid in establishing a public health nursing service. Bills relating to medical inspection in schools, school physicians or school nurses, were introduced in Connecticut, New York (passed), Rhode Island and Minnesota. Oregon passed a law requiring physical examination of all school children during the first month of the school year, providing no objection has been made by the parent. Bills improving birth and death registration passed in Michigan and Vermont but failed in Maine. The status of such bills in Oklahoma and Pennsylvania is unknown. South Dakota passed a law requiring physicians and others to employ certain methods for the prevention of blindness and infections of the eyes of newborn infants. West Virginia introduced bills for licensing and registering midwives. Iowa and South Dakota passed new regulations for the control and inspection of maternity hospitals.

Physically Handicapped Children.—Bills relating to crippled children were introduced in Arkansas, Illinois, Ohio, Oklahoma, and Pennsylvania. Pennsylvania appropriated $250,000 for a state hospital for indigent and other children with surgical tuberculosis and allied conditions. Connecticut, New York, Ohio, Oregon and Pennsylvania passed laws promoting the education of blind, crippled and otherwise physically handicapped children. The Pennsylvania law provides for the enumeration of children between the ages of six and sixteen, who, because of apparent physical or mental condition, are not being properly educated, and for authorizing home teaching by legally certified teachers as an alternative to public school or institutional instruction.

Mentally Defective Children.—Bills relating to the examination, care and training of the mentally defective have been passed by Iowa, Indiana, Michigan, Minnesota, New Mexico, Oregon, Pennsylvania, and South Dakota, and were also pending in Kansas, Nebraska, Ohio, and Wisconsin. Bills for the sterilization of mental defectives were introduced in Colorado, Idaho, Maine, Michigan, Minnesota, New Jersey, Ohio, and Rhode Island. The Idaho, Maine, and Michigan bills are known to have passed and the Rhode Island one to have failed.

Juvenile Courts.—A few bills which would destroy or weaken juvenile courts have been introduced, but so far as present information indicates none has passed.

Dependent Children.—Bills relating to dependent children were introduced in various states. Iowa passed a law requiring the annual licensing of childcaring agencies, institutions and boarding homes. Pennsylvania passed a law providing for the licensing and for regulation of boarding houses for children under three years of age by the state department of welfare. Bills relating to mothers' pensions were introduced in a number of states. South Dakota passed a law making the existing mothers' pension laws applicable to unorganized counties. North Carolina cut its mothers pension appropriation from $50,000 to $30,000. North Dakota passed a law making more strict the procedure through which pensions are obtained.

Adoption.—Acts relating to the adoption of children were enacted by New Mexico, New York, Pennsylvania, and Rhode Island, but failed to become law in California, Connecticut, and Iowa. The fate of the Wisconsin bill is unknown.

Children Born Out of Wedlock.—Laws relating to illegitimate children were passed in New Hampshire, Oregon, and New York. New Hampshire provided that divorce shall not affect the legitimacy of a child born in wedlock unless the decree expressly so provides, and also that children born of a marriage entered into in good faith are legitimate even though the marriage is annulled. Oregon decreed that children of unmarried parents who live as husband and wife for over one year in the State of Oregon shall be legitimate, provided neither parent is married to a third person. New York passed a law changing the procedure of establishing paternity and another law designed to eliminate the word "illegitimate" from school books and statutes and to substitute therefor the expression "children born out of wedlock."

Delinquents.—Measures relating to commitment of delinquent minors and to the establishment and regulation of industrial schools for such persons were pending in a number of states.

Recreation.—Bills to regulate and license all dance halls and amusement halls were introduced in Colorado, Idaho, Kansas, Maine, Minnesota, Ohio, Oregon, Pennsylvania and Wisconsin. The Oregon bill is known to have passed and the Maine bill to have failed. The Illinois bill, which passed the Senate, would prohibit persons under 16 years of age from being present in any public dance hall outside the limits of the city, village or town. The Pennsylvania bill would make it unlawful to permit any person under sixteen to attend a public dance after 9 p. m. Indiana and Vermont have passed laws authorizing the extension of systems of public recreation.

Marriage License Regulation.—Bills relating to marriage license regulations were introduced in a number of states, but according to all available information no important measure was enacted into law.

Maine Legislates Against Spread of Venereal Diseases.—As an additional measure for the protection of the community from venereal infection the Eighty-Second Legislature of the State of Maine passed an amendment whereby superintendents of State, county, and municipal charitable or correctional institutions are required to report to the State Department of Public Health any inmate about to be released and who is afflicted with a venereal disease in an infectious form. The report is to be made not later than fourteen days before the estimated date of release, so that the State Department of Public Health may "take necessary measures to protect others from such infection."

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Gonorrhea Apparently Increasing in New York.—Gonorrhea and syphilis not being reportable directly as such to the State Department of Health, the incidence can only be judged by the number of blood specimens or smears which are reported as positive by approved laboratories, says *Health News* for July 6, 1925. The consensus is that gonorrhea is several times as prevalent as syphilis. The figures of this State do not show that the laboratories have received as many specimens for examination for the organism of gonorrhea as for the Wassermann test. The percentage increase of specimens submitted for the first three months of 1925 over the corresponding months of 1924 is strikingly noticeable as shown below:

State Laboratory, Albany, January, 19.69 per cent.; February, 37.45 per cent.; March, 45.33 per cent. Branch Laboratory, New York City, January, 60.34 per cent.; February, 27.69 per cent.; March, 9.88 per cent.

The increase in positive cases was ten per cent. upstate and five per cent. for New York city over the corresponding quarter of last year. This apparent increase may be due to 1, a greater use of laboratory facilities for diagnostic purposes; 2, patients seeking treatment from reputable physicians instead of from drug stores, quacks; 3, increased promiscuity resulting in an actual increase in the incidence of gonorrhea.

Milk Regulation for Panama.—An executive decree regarding milk regulations in the cities of Colon and Panama has been issued recently by the President of the Republic. An abstract of the decree is as follows:

All milk stored, sold or offered for sale, in the cities of Colon and Panama must not contain water or any other extraneous substance added, and must contain not less than three per cent of butter fats and not less than 12 per cent of total solids, nor more than 88 per cent of water, and shall be pasteurized. These standards may be modified and other standards or tests of purity and fitness may be prescribed by the Chief Health Officer of The Panama Canal at his discretion and such modifications or other standards or tests shall have the same force as these regulations. Any milk not conforming to the standards specified above except as hereinafter provided shall be regarded as adulterated, impure or unfit for human consumption and may be seized and destroyed by the Health Officer or his representative at time of inspection in the manner provided for adulterated milk.

Modified milk, skimmed milk, buttermilk and other milk preparations not conforming to the above section, may be sold in the cities of Colon and Panama under a special permit therefor issued by the Health Officer at his discretion, provided such modified milk, skimmed milk, buttermilk or other milk preparation bears a label clearly setting forth its character.

Production of Tetanus Antiserum in Cattle.—Rudolf Kraus (*Wiener klinische Wochenschrift*, January 17, 1924) showed that neutralizing substances against diphtheria antitoxin were demonstrable in the blood of old horses and also the same substances were demonstrable against tetanus antitoxin in the blood of old cattle. These physiological antitoxins are the cause for the greater resistance of old animals aginst these corresponding toxins than that of younger animals. The analogue in man is the Schick reaction. Consequently it is possible to immunize horses against diphtheria and cattle against tetanus with toxins. The antitoxin values with this immunization are just as great in the old animals as in the young animals. Therefore the production of tetanus antitoxin in cattle is advisable. The tetanus antiserum of cattle produces serum sickness much more rarely than that obtained from horses and it should therefore be tried for preventive as well as curative purposes.

PREPARATION
NUTRIO PERFECTA
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Overcrowding Facilitates Spread of Social Diseases.—The National Antislum League of Paris in its recent report states that overcrowding is rampant in certain sections of that city and that it may be viewed as the cause of social disintegration and the moral downfall of the family. "The danger of promiscuity," says the report, "naturally occurs when parents and children sleep in the same room and elder and younger brothers—and very often brothers and sisters—sleep in the same bed."

The housing difficulties in Germany, according to an abstract in *Social Pathology,* issued by the United States Public Health Service, have much to do with the increase of venereal diseases, particularly among children. Due to overcrowding entire families have been infected, and a coincident laxity of moral standards has been found. One report states that a family of nine slept in one room, two married couples being among the number. An editorial in *National Health,* published in London, states that "We are not likely to attain a full measure of success in the control of venereal disease until we have arrived at a solution of the housing difficulty."

But the incubators of lewdness and its frequent associates—gonorrhea and syphilis—are by no means limited to the lower strata of society. Promiscuity is very diffusible, and one of the most essential as well as productive measures for health maintenance is the effort to combat venereal diseases by both mental and physical hygiene. The two leading British societies for the prevention of these diseases are now in accord as to the efficacy of personal cleanliness and disinfection, in the prevention of venereal infection.

Widespread education by publicity regarding the great scourge of the venereal diseases as they affect the child, the family and the State, and the conditions influencing their spread and prevention is very productive of good results and is universally recognized as essential health work. The *Washington Times,* June 26th, gives publicity editorially to "The Curse of Deafness," and points out the causative relation of syphilis to certain types.

The Virtue of Irresponsibility.—If one may judge by their actions, the god of the Gringoes is the clock says the Latin-American correspondent of the MEDICAL JOURNAL AND RECORD. All their waking hours, they worship at his dial, slavishly guided by the auguries of two mechanical hands, and the obsession is so great that special means are provided wherewith to consult this metallic god at night. The fetish of being on time is exalted to the level of a virtue, and we live in perpetual fear lest we shall be late.

As a result, we waste much time and many golden opportunities for blissful dawdling because our phobia urges us to such a degree that we are always early. Our whole existence is hedged about by minutes and seconds, and we are unable to relax into that agreeable and soul satisfying state wherein time is not.

Out of this horological worship grows our sense of responsibility. If a North American says he will do a thing, he generally does it. If he promises to meet you at the spot marked X in the diagram at 10 o'clock ante meridian, Standard time, on April 5, 1924, he will be found standing at the exact focus of convergence at 9:55 a. m. of the day set. We hold this to be admirable and strive to indoctrinate the young with the beauties of promptness, the obligations of engagements, and the sacredness of accuracy. Any infraction of these tenets, we regard as evidences of complete depravity. If we say "there are ten dogs," the statement must be exactly true. We frown upon the addition of a single dog for the embellishment of the narrative, preferring in our besotted accuracy, "nine dogs and a pup" to "eleven vicious bloodhounds." We look askance at the romancer, holding him only one degree less abased than the unpunctual. For the purposes of that brand of humor which we consider particularly our own, one may engage in exaggeration, but it must be carefully labelled as such. In this manner, playful liberties may be taken with truth, but to miss the 7:38 train is a serious lapse from responsibility which will require considerable living down.

Responsibility, that mental infection which was introduced in Colonial times under the name "New England conscience," has gradually spread among the population until it has invaded that fair land where in bygone, sinful days, mintjuleps used to grow; it is throttling the embroidered narrative of range and mine and the panegyrics of the Los Angeles realtor have been brought low. We have become the slaves of the clock and the arch disciples of the square, the plumbline and every other diabolical instrument of precision.

But, fortunately, the Rio Grande has thus far proven impassable and that happy region which extends thence southward to Tierra del Fuego, bows not the knee to these compelling gods. How thrice blessed is it to live in a land where watches are largely worn for ornamental purposes! where it is considered a mark of good breeding to arrive at any function at least thirty minutes (the exact degree of tardiness is of no moment provided it be of respectable length) after the appointed hour! where desiring dinner guests at eight o'clock, one invites them for seven! How joyful is the sensation of traveling on trains which never depart on the scheduled hour, and how boring is the misguided *macho* who always insists that engagements shall be met promptly.

Our brethren who live between Cancer and Capricorn regard as eccentricity the point of fine honor which our delegates observe at international congresses, by arriving at every formation at the exact hour set. Theirs is a more logical and praiseworthy plan permitting completed slumber, leisurely dressing and an unhurried breakfast before attending morning sessions, and a peaceful lunch followed by a refreshing siesta preparatory to the business of the afternoon.

Making an engagement has not been brought to the sordid level of a contract or the sacredness of a religious ceremony in those climes. It is, instead, a delightful conversational interlude which implies no obligation to either party. If one happens to think about it afterward and it is entirely convenient, the rendezvous is visited quite casually, perhaps an hour after the time agreed upon. It is not bad form to

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. DURING PREGNANCY

an increase in the development of poisons within the expectant mother's body is inevitable. Therefore, interference with free elimination from the bowels always presents a special menace from the essential increase in the retention of toxins with all their possibilities for harm to both mother and offspring.

Fortunately, *in AGAROL COMP.* the practitioner has an ideal remedy, that not alone will afford prompt intestinal elimination, but used for a reasonable period, will soon restore the physiologic activity of the bowels, thus assuring normal evacuations that will follow regularly and thoroughly without the aid of further medication.

Entirely free from griping or pain, or any other objectionable effect, AGAROL can be used at any stage of pregnancy with every confidence in its safety and efficiency.

REMEMBER—Agarol is the original Mineral Oil—Agar-Agar Emulsion, and is perfectly stable, odorless and palatable.

A liberal supply for testing will be sent to physicians on request

113-123 West 18th Street **New York City**

wait a little while for the other engager, if one wishes. Should he be already there or should he stroll in, the thrill of the unusual is added to the pleasure of the meeting. Should he not come at all, the matter is dismissed from the mind and the *faux pas* of mentioning his remission is not committed.

Equally liberal is the custom with regard to statements of number, size and quality. One catches one hundred fish *mas o menos,* a farm is a thousand *hectares mas o menos,* a thing is perfect *mas o menos.* We call it "more or less," but always with subconscious apology. The *mas o menos* habit has no such restrictions. Not that one wilfully commits an untruth; ah no, any such imputation, if such there rudely be, is dispelled completely by that useful phrase.

This delightful practice is the woof and warp of an untrammeled social fabric. One must be careful not to admire any possession of another too warmly, since it will then be given to him. To refuse would be a deadly, but none the less satisfactory, insult. To accept it is dangerous, unless one is prepared to have some cherished property extravagantly admired in turn.

But there is a way out of this dilemma. The giver agrees to send the gift by a servant, an unfortunate being who invariably perishes en route or runs away with the precious present. Perhaps the article is broken, burned or otherwise destroyed. The accidents which may occur to the gift and its bearer are myriad—all of this if one is so tactlessly Gringoesque as to mention the matter—in fact they are incredible!

In cases like this, in fact, in any case in which an agreement has not been carried out, the rule of procedure is simplicity itself. The party of the first part makes an explanation of any sort, care being taken that it shall be in no particular true. The party of the second part answers in kind. Each understands perfectly that no vestige of truth has violated the amenities of social courtesy, and thus, what might easily have proven an annoying incident has been transmuted into a pleasant function.

An American of that scrupulously accurate type so galling to the lover of perfect irresponsibility, was receiver of a tropical bank which had undergone untimely dissolution. Among the assets were a large number of notes, endorsed by many of the best people of the city. The receiver called upon them to meet the notes.

"But, my dear Mr. Receiver, I must protest. I have done business with this bank for many years. It is an outrage that an old customer should thus have his written word questioned. I have endorsed the note. That should be sufficient!"

"I'm sorry, Mr. Endorser. You're no longer doing business with the bank, but with the Court which I represent. The signer of the note can't pay it. You can and must. If you didn't intend to do so, you shouldn't have endorsed it."

"But, my dear Mr. Receiver, you don't understand. That endorsement was merely a social courtesy!"

Three stenographers were engaged to take the discussions at an international meeting. The manuscript, when received, was found to lack about two thirds of completeness. A distressing situation this, but the editor of the proceedings interpolated from his inmost imagination those remarks which everybody should have made, with the result that each speaker marvelled at the brilliancy of his discussions as printed. Thus, responsibility was met perfectly by a thorough irresponsibility which could have only been excelled by neglecting entirely the preparation of the proceedings.

But we must not critically regard everyone who lives in Pan America as less responsible than are we. To make such a sweeping classification would be as unjust as it is unkind. Their responsibility takes another form than ours. It would be hard to induce one of them, save for motives of politeness, to imbibe the potentially dangerous beverages which many of our thirsty citizens have taken to drinking since the Volsteadian era. They are amazed at the way in which the average United Statesan, even some of our lawmakers, rush for a bar the minute they land in a Latin country. In matters of true courtesy their sense of responsibility might well serve us as a pattern.

This may be illustrated by the way in which a dear old Mexican lady inquired after the health of her American friend and her numerous progeny. Apropos of this, it may be noted that the word "Gringo" grew out of the Mexican War, just as did the word "cocktail." We altered "coquequail" to "cocktail," and when our soldiers were filled with this then new concoction they so continuously sang "The green grass grows all 'round," that the natives thought it was our national anthem. "Green-grass-grows," sung under these circumstances, contracts neatly into "greengo" and hence our appellation.[1] Similarly, another of our frequently and forcibly used expressions has quite unmaliciously been applied to us, and we are known commonly as "Goddames." But, back to the illustration—our dear old Mexican lady meeting her American friend, inquired solicitously after her health, that of her husband, her father, her mother, and as a peroration said, "And how are all the little Goddamitos today?" Social responsibility to the ultimate!

The antidote for the infection of punctuality, accuracy and overbearing responsibility, is irresponsibility. Happy the land where nobody is driven by the devil which resides within the clock, artfully hidden behind the smug primness of its china face: how blessed is he who has no curse of exactness laid upon him, but is permitted to follow his own unfettered fancy as he wills: how much liberty has he who is not borne down by the oppressive weight of responsibility!

So far as the United States are concerned, it appears as though the infection is incurable and incapable of eradication. Steadily, it is gaining ground, and without doubt it will one day engulf us all.

For us the outlook is most gloomy, but there is one gleam which illumines the darkness—not far away are happier nations where irresponsibility and other things still flourish, and are there to be had by the seeker after freedom from the irksomeness of life.

[1]One of those disagreeably accurate persons, whose mission in life seems to be the destruction of picturesque myths, states that "Gringo" is a corruption of *Griego,* i.e., Greek, connoting that what a person says "is all Greek" to his hearer.

CARDYSATE

A cardiac stimulant and tonic prepared by dialysis of the juice of fresh digitalis leaves

PHYSIOLOGICALLY STANDARDIZED

FREE FROM FATS, RESINS AND COLLOIDS

REPRESENTS THE WHOLE DRUG

NEW YORK

Promises Upset in Heredity Theory.—Modern theories of heredity may be refuted by experiments now being made at Stanford University by Professor L. L. Burlingame of the Department of Biology on a plant known as the Clarkia. On first investigation this plant appeared to be contrary to the accepted laws of heredity; however, experiments are being continued to prove that that is merely an explainable deviation.

The present theory is that in every plant or animal there is a definite number of units, known as chromosomes. These units work in pairs. Man has forty-eight of these pairs. These chromosomes furnish the means for transmission of hereditary characteristics. The Clarkia appears to have a varying number of pairs. The correct number seems to be four, but there have been counted from five to eight pairs in the sex cells and from two to seven in the body cells. This is in defiance of all knowledge of heredity.

Professor Burlingame discovered this wide variation while experimenting in hybridization of this plant in the garden. Upon noticing the inconsistency of the plant, he began a thorough study of its properties. He is attempting to prove that it may be explained by the chromosomes having broken up into smaller particles, but still remaining unchanged in their original quantity. If this were true, the smaller parts would be the same size as the sum of the proper number of full sized chromosomes. Owing to the irregularities in their shapes, however, great difficulty is being found in measuring them.

This is the only known case in which the number of chromosomes varies through there may be others yet undiscovered. Professor Burlingame believes that the explanation will be in accordance with the laws as they are now understood, and is attempting by experiment to confirm his theory.

If You Use It Once--

you will readily understand why so many physicians in choosing a reconstructive tonic invariably order or prescribe

Gray's Glycerine Tonic Comp.

Formula Dr. John P. Gray

Its results will not be uncertain nor delayed and like so many other practitioners, you will be impressed with their prompt, positive and permanent character. Best of all, your patients will be as quick to note its effects and appreciate the substantial nature of the benefits they will uniformly obtain.

The fact that Gray's Glycerine Tonic has been serving the profession for over a third of a century and that every year witnesses its increased use by discriminating medical men, "tells its own story".

The Purdue Frederick Co. 135 Christopher St., New York City

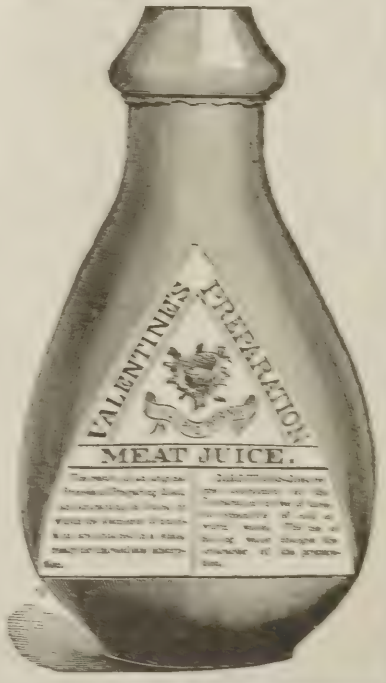
Valentine's Meat-Juice

In **Diarrhoea, Dysentery** and **Cholera Infantum**, in the **Wasting** and **Febrile Diseases** of **Children**, and in the treatment of **Weak Babies**, the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been demonstrated in Hospitals for Children.

Diseases of Children.

W. T. Watt, M. D., *Dispensary Imperial Medical College, Dundee, Chemist:* "In cases of Infantile Diarrhœa, which weakens and emaciates a child rapidly, I have found VALENTINE'S MEAT-JUICE a great stimulant and quick restorative of vitality. Three years ago, when an epidemic broke out in Tientsin, I ordered my staff to try your MEAT-JUICE, which justified all expectations, having been satisfactory to patients and physicians alike."

Dr. Calatraveno, *Late Physician of the Children's Hospital, Madrid, Spain:* "I have employed VALENTINE'S MEAT-JUICE most successfully in cases of convalescence from infectious diseases, and it is especially beneficial for children suffering from urinary weakness caused by extreme debility, as in every case it acted remarkably in restoring their strength with notable rapidity."



Physicians are invited to send for brochures containing clinical reports

For sale by American and European Chemists and Druggists.

Miscellany.

Puerperal Hemiplegia.—James E. Talley (*Medical Clinics of North America,* November, 1924) states that puerperal hemiplegia has been attributed to thrombophlebitis, embolism, cerebral congestion and edema, cerebral hemorrhage, brain abscess, and even severe anemia. It is a rare condition, and yet enough cases are reported with autopsies to indicate that thrombophlebitis and embolism are the underlying causes more often than cerebral hemorrhage. It is usually a hemiplegia. Both extremities need not be equally affected, though the arm is apt to suffer most. Monoplegias occur. A primary partial aphasia is sometimes the forerunner. Just how often there is a primary phlebitis in pelvis or leg, frank or concealed, is uncertain.

In puerperal infections, all the elements necessary to thrombus formation are present—bacteria to injure the intima, sluggish circulation to favor the deposition of blood platelets on the necrotic wall, which sets in motion the chemical changes leading to clotting. Streptococci, staphylococci, and other pyogenic bacteria are chiefly concerned, and they all show a great predilection for the veins. Puerperal thrombophlebitis may be found in uterine, pelvic, iliac, femoral, saphenous, or any veins in these regions. Disturbed blood flow appears to be an important factor in thrombus formation. The thrombophlebitis may remain localized in the lower part of the body, or it may spread by way of the blood stream of lymphatics. The degree of latency in pelvic thrombophlebitis is remarkable.

Cerebral embolism is rare. A simple embolus interfering with less than an entire lobe of the lung may give rise to little circulatory disturbance owing to the rich anastomosis of the pulmonary artery. Large emboli block the pulmonary artery and kill, not so much from their influence on the lung as from the sudden strain thrown upon the heart. Lesser emboli give a picture of pleurisy or pneumonia, perhaps pulmonary edema, or they may remain quiescent in the spleen or kidney. Some cases show at the same time pulmonary embolism, hemiplegia (cerebral embolism) and embolism of superficial veins. These multiple emboli arise in a recurrent endocarditis. Infarction of the brain is extremely common; meningeal involvement is symptomless. If a small vessel alone is involved, there may be a temporary lapse from consciousness or none at all. There may or may not be variously localized palsies. If the branch is large, symptoms like apoplexy occur, unconsciousness, a flaccid palsy more widespread at first, and a limited palsy will persist corresponding to the part of the brain destroyed. If the emboli are septic the first effect is mechanical, and eventually these areas resemble an abscess. This explains the transitory aphasias and hemiplegias found in some histories. Puerperal embolism should lead to the search for an endocarditis recurrent during pregnancy or arising from puerperal infection. The infection may spread through the capillaries and lymphatics.

Cerebral hemorrhage may occur before, during, or after delivery. Hemiplegia occurring during the second or third weeks postpartum is almost always due to infection; later, and even during the first week postpartum, it may be due to infection. Distinct mitral disease, especially stenosis or a history of acute rheumatic fever or chorea, are very suggestive. Causes for defective bloodvessels must be borne in mind—lues, nephritis, and eclampsia. The attacks following delivery are more apt to lack uremic symptoms. The hemorrhage and palsy develop usually in close relationship to convulsions. In these eclamptic or albuminuric palsies hemorrhage is not always the basis; transient congestion and edema of the brain sometimes give origin to the socalled serous apoplexies, whose symptoms fluctuate and improve so rapidly that they may be thought hysterical. Occasionally varices are responsible for these hemorrhages. Hemorrhage from the choroid plexus is also described.

Brain abscess causing puerperal hemiplegia is usually a part of a frank puerperal septicemia. A marked anemia due to severe postpartum hemorrhage may be one of many factors leading to puerperal hemiplegia, but neither alone or combined are they sufficient to stand as a sole etiological factor.

The differential diagnosis between cerebral thrombophlebitis, embolism, hemorrhage, or serous apoplexy is difficult if not impossible. In cerebral thrombosis the presence of a known phlebitis is suggestive. Ordinarily the palsy is usually less brusque than in hemorrhage or embolism. There may be the antecedent headache, slight fever, accelerated pulse, paresthesia, paresis, and aphasia. The hemiplegia is, on the whole, slower of development. Embolism, like hemorrhage, is brusque. The presence of a phlebitis, known or suspected, or of an endocarditis, especially mitral, are more than suggestive. Leftsided occlusion with rightsided hemiplegia is more often due to embolism. Cerebral hemorrhage is sudden, the palsy complete early. Diseased vessels, as in lues and nephritis, are suggestive. In eclampsia the presence of nausea, vomiting, visual disturbances, edema, albuminuria, if present, are all helpful. The palsy due to cerebral congestion or edema in this connection may be transitory or changeable.

The prognosis of puerperal hemiplegia is grave but not hopeless; the permanent disability is never so great as the initial palsy. The treatment is mainly a question of asepsis, and of as little vaginal examination as possible. Massage and manipulations in phlegmasia are absolutely contraindicated.

A Biophysical Law Governing Surgical Mortality.—G. K. Crile (*Surgery, Gynecology and Obstetrics,* April, 1924) says that although the electrochemical theory interprets well the normal and the pathological phenomena of man and animals; although the numerous predictions based upon this theory were established by the more exact methods of physics; although it has furnished a plausible suggestion as to the line of evolution from the atom to man; although the theory has stood the crucial test of the surgical clinic by providing a scheme of management which has produced the shockless operation, the theory is not yet proved, and will not be proved until the equivalent of a living cell is constructed; until the equivalent of life is artificially made. Nevertheless, from previously accepted facts, from clinical observations, and from the evidence of experimental researches in our laboratory of biophysics he concludes as follows: 1. That electrical phenomena are coexistent with living phenomena because electricity is detected in every living plant or animal and is absent in the dead. 2. That electricity is manifested in every act of the living and is probably the socalled spark of life. 3. That there are great numbers of different kinds of electric circuits in animals. 4. That the source of electricity in the cells is oxidation. 5. That oxidation in the cells of the organism is initiated and governed by electricity. 6. That electricity is accumulated on the lipoid films of the trillions of cells. 7. That each of the trillions of cells is a diminutive electrochemical unit. 8. That during life there is a difference of potential, a state of unbalance within the organism. 9. That death is equilibrium of potential. 10. That there is a universal pattern of the living in the form of bipolarism. 11. That in the nonliving no less than the living exists the universal pattern of bipolarism. 12. That the pattern of bipolarism runs in continuity from atom to man. 13. That man is an electrochemical mechanism, a giant ameba climbing up the slippery banks of time.

Surgery of the Thorax.—D. B. Phemister (*Surgery, Gynecology and Obstetrics,* April, 1924) says that expansion of a collapsed lung in acute empyema with drainage where stabilization of mediastinum has occurred may be the result of three factors: 1. The pull of the contracting granulations on the visceral pleura at its reflection on to parietal pleura as the two layers fuse, and the cavity is gradually obliterated. 2. The positive pressure within the collapsed lung produced by the entrance of air from the opposite side during forced expiration. 3. The negative pressure in the empyema cavity present during inspiration, when the diameter of the drainage opening is smaller than that of the main bronchus on the affected side. Of these three factors, the pulling out of the lung by the healing granulations is the one of greatest importance. With the establishment of suitable conditions, the empyema wound heals and the cavity is obliterated by granulation tissue and the fusion of its walls. Free drainage does the most toward procuring healthy granulations on the pleural surfaces. The author doubts if anything is accomplished by irrigation of the pleural cavity in acute empyema, except in those cases where there are large amounts of filbrin or in the very exceptional cases where sloughs are present, and then the irrigations do not need to be continued beyond the time of their removal. Fibrin is not nearly as harmful in empyema as some have imagined.

PARATHYRIN

A Solution for Intramuscular or Intravenous Injection Containing the Active Hormones of the Parathyroid Bodies

Parathyrin is used in the treatment of tetany, paralysis agitans, chorea and other conditions associated with a functionally deficient calcium metabolism such as tuberculosis, osteomalacia, varicose and indolent ulcers.

It has also been used experimentally in certain forms of deranged fat metabolism; in conjunction with insulin in coma of diabetic origin, as well as most convulsive states and in cases of diabetes showing acetonuria.

Ordinarily two doses each week are quite sufficient, but in extreme cases the doses of 1 cc may be given daily or on alternate days for several doses.

The same preparation in triple strength is likewise available for the unusual cases, but the single strength solution is supplied on all unspecified orders for Parathyrin.

Box of ½ dozen 1 cc. ampoules..... $2.00
Box of 100, 1 cc. ampoules..... 30.00

PARATHYRIN INCREASES BLOOD CALCIUM

A Typical Example of the Effect of Parathyrin When Administered to Normal Rabbits Kept on a Constant Standard Diet.

Each rabbit received three doses of single strength Parathyrin subcutaneously at three-day intervals, and were bled for the second test three days after receiving the last dose.

Rabbit No.	Blood Calcium Before Treatment	Blood Calcium After Treatment	Increase in Blood Calcium	Percentage Increase
1	19.5 mg.	22.4 mg.	2.9 mg.	14.9%
2	18.0 mg.	22.0 mg.	4.0 mg.	22.0%
3	15.5 mg.	19.1 mg.	3.6 mg.	23.0%
4	17.5 mg.	20.9 mg.	3.4 mg.	19.0%

Pharmaceutical and Biological Laboratories

DYSCHEZIA

Dyschezia due to functional causes is promptly relieved, and normal action of the bowels gradually restored by the systematic use of

AGAROL

The rational composition of this exceptional preparation cannot fail to impress the thoughtful practitioner. Every ingredient fills a definite purpose, and in their composite influence so closely duplicate natural conditions that the bowels act normally without the least griping or other objectionable effect.

The more familiar the practitioner becomes with Agarol, the more he will appreciate its superiority to ordinary laxatives. A trial in some intractable case will tell him why.

AGAROL is the *original* Mineral Oil—Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contra-indications; no oil leakage; no griping or pain; no nausea or gastric disturbances—Not habit forming.

WILLIAM R. WARNER CO., Inc.
Manufacturing Pharmaceutists since 1856
113-123 WEST 18th STREET NEW YORK CITY

Fate of Fractured Carpal Navicular.—K. Speed (*Annals of Surgery,* October, 1924), after a study of a series of these fractures at varying periods after the original trauma, says that the original fracture interference with the blood supply cuts off nutrition to the cancellous structure. Should the condition be recognized and sufficient rest be offered the bone, revascularization with a saving of the bone may result. In the neglected cases bone death rapidly ensues, and the process of malacia or osteoporosis begins, ending in complete absorption of the main mass of the bone. As far as the author has been able to determine we must revise our ideas about the influence of the synovial fluid on these fractures. It has formerly been taught that the irritative effect of the synovial fluid led to destruction of the bone, but the author's sections seem to prove just the opposite, namely, that the synovial fluid offers sustenance to the superficial layer of cartilage and cortical bone and maintains the nutrition of the cells for years. The new bone formation from surrounding bones must be a reaction to the presence of the dead navicular and is protective, that is, it is a natural effort to stiffen the wrist to inhibit motion and consequently relieve the patient from pain. Using the clinical and pathological evidence obtained from a series of these injuries, there is no hesitation in advising immediate and prolonged splinting of the fractured and undislocated navicular. If dislocation of fragment has occurred, the author believes operative removal is indicated. Certainly in all fractures unrecognized more than a few days operative removal of the whole bone promises the quickest return of function in the hand and wrist. Nothing is gained by delay.

Chronic Mastitis.—Geoffrey Keynes (*Lancet,* September 1, 1924) states that the breast is a secreting gland which shows periodical activity from birth to the menopause. The normal, nonlactating breast has no outlet through the nipple for the discharge of its secretions. Secretion must therefore be balanced by reabsorption. Chronic mastitis is manifested by dilatation of ducts and acini, accumulation in them of the products of epithelial activity, infiltration with lymphocytes, fibrosis, and epithelial changes. The distribution of all the processes is very erratic. Chronic mastitis is commonest in women, but occurs also in men. It first appears in the second decade, but is most often seen in the fifth. It appears earlier in single women than in women who have borne children. The condition is not bacterial in origin, toxemic or traumatic, nor is it related to involution changes in the breast. The cause of chronic mastitis is probably to be found in chemical irritation due to stagnating secretions and epithelial débris. This cannot be proved until the chemical changes have been investigated. Chronic mastitis, though very often associated with carcinoma, has not been proved to be due to the same cause. In its more advanced stages it must be treated by operation. At an earlier stage natural drainage may be tried, or x rays may be applied.

Jacobaeus Method of Intrathoracic Cauterization of Pleural Adhesions in Pneumothorax.—O. Weber (*Schweizerische medizinische Wochenschrift,* October 30, 1924) reports upon five cases in which pleural adhesions were cut with a galvanocautery under the guidance of a thoracoscope. After the localization of the adhesions in the roentgenogram, the apparent course of the visible adhesions are projected upon the skin with a skin pencil. The site of introduction of the thoracoscope is determined by the position and the course of these adhesions. It should be selected with a view to reaching all the existing adhesions. The author prefers the third to the fifth intercostal spaces, between the middle axillary and the mamillary lines, for the introduction of the thoracoscope and the cautery. Local anesthesia is used.

One should not be surprised at finding more adhesions on thoracoscopy than are demonstrable in the roentgenogram, and also differences in the form and thickness of the individual bands. The cautery point is then introduced through the thoracoscope and the bands of adhesions are divided a millimetre at a time. With the proper regulation of the heat the coagulation process is a gradual one and all bleeding is thereby controlled. The cautery should be moved about only under direct vision to avoid injury of normal tissues. In order to avoid emphysema of the soft parts it is necessary to maintain the pneumothorax pressure around zero or slightly negative before withdrawing the instruments, and in the presence of an existing irritative cough sedatives should be administered. The thoracoscopy may be associated with a short, severe clonic spasm in the arm on that side when the parietal pleura is touched with the thoracoscope in the region of the axilla. The operation may be followed by serous pleurisy and less often by empyema. Nevertheless the author believes this procedure to be preferable to thoracoplasty if complete collapse of the lung can be obtained after it.

Primary Carcinoma of the Lung.—K. Playfair and C. P. G. Wakeley (*British Journal of Surgery,* October, 1924) present the following conclusions:

1. Primary carcinoma of the lung, while still correctly regarded as a rare condition, is probably of more frequent occurrence than is usually admitted. Cases reported from America during the past five years are very much more numerous than in this country. This may be a true indication of its relative incidence in the two countries, but it is to be doubted if it is so. Absence of routine autopsy here, and perhaps a reluctance to record such cases, may account for the apparent difference.

2. The etiology is little understood; but the fact that chronic inflammatory affections precede this type of carcinoma may be a factor of importance, as is frequently the case in carcinoma elsewhere. Chronic bronchitis originating from respiratory lesions of influenza may be one of the most important precursors of pulmonary carcinoma.

The pathology is still obscure. Although many cases are readily classified histologically, many others, especially advanced cases, must remain unidentified as regards their exact origin.

3. We would emphasize the need of a constant consideration of primary pulmonary neoplasm in all cases presenting any chronic lung symptoms, such as shortness of breath, cough, hemoptysis, and thoracic pain. It is upon an early and correct diagnosis that the future of surgery and radiotherapy in treatment must depend.

Diagnosis must primarily depend on a detailed and correct correlation of the history and clinical observations, while radiography, a useful adjunct at times, is too often unreliable. Degenerate carcinoma cells when present in the sputum are diagnostic, but this is a rare occurrence, and may be overlooked during the routine examination for tubercle bacilli.

4. Surgery, with intratracheal anesthesia, and possibly the simultaneous administration of radiotherapy, offer the only means of eradication of this disease; but progress must be slow until the early symptomatology is more generally recognized.

The Relationship of Chronic Endocervicitis to Focal Infection with Special Reference to Chronic Arthritis.—Laura M. Moench (*Journal of Laboratory and Clinical Medicine,* February, 1924) studied bacteriologically a series of eighty-two miscellaneous cases with leucorrhea, thirty-eight strains of which were used for animal inoculation. In these studies the streptococcus was the organism of importance, and the more saprophytic flora played relatively unimportant parts. The histories of twelve patients are given who showed joint conditions and an infection of the cervix, whereby it appears that cervical streptococci have a selective affinity for the joints, suggesting a relationship with Rosenow's elective localization theory in focal infection. The antigenic properties of the cervical streptococci suggest low virulence, but high specificity of these strains. A modification of Kennedy's method of interstitial injection substituting equal proportions of gentian violet and neutral acriflavine in varying dilutions for his ethyl alcohol was used for treatment. Several cases studied were rendered bacteria free following a single injection, and a second injection usually rendered the canal sterile.

Carbon Dioxide Treatment in Acute Alcoholic Intoxication.—F. T. Hunter and S. G. Mudd (*Boston Medical and Surgical Journal,* June 5, 1924) suggests that, inasmuch as the majority of deaths from alcoholism at the present time result from the ingestion of lethal doses of alcohol and not from particular poisons in the beverage, carbon dioxide administration would be of value in the treatment of all cases of alcoholic coma. In cases of methyl alcohol poisoning carbon dioxide would be even more efficacious as, due to its lower boiling point, it has a higher partial pressure than ethyl alcohol, both being at the same concentration.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Causes of Loose Bodies in Joints.—D. B. Phemister (*Journal of Bone and Joint Surgery*, April, 1924), sums up his study of the etiology as follows:

From a consideration of the evidence for and against the various theories of causation of the classical loose bodies that have here been enumerated, the author is forced to the conclusion that an entirely satisfactory explanation has not yet been offered. The lesion does not seem to be a complete intraarticular fracture. If it were, fragments detached from sources other than the lateral surface of the mesial condyle of the femur, the patellar surface, and the capitellum of the humerus should as regularly persist as loose bodies in the joint, which is not the case. Incomplete or subchondral fracture passing between cartilage and bone or through bone is a more plausible explanation, although there are many objections to it. Nonunion would have to follow and the cartilaginous bridge would be severed subsequently, either by trauma or by absorption. Nutritional disturbance in the partially detached portion would favor the occurrence of nonunion, but the partial fixation would greatly increase the chances of union with its bed. It is possible that the cause of nonunion is general and is not understood, as is the case in a certain percentage of ununited fractures of the shaft. Articular cartilage is devoid of nerve supply and there is extremely little sensation in the cancellous bone which it overlies. It is possible that a fracture of the articular surface might result from undue violence and be accompanied by little or no pain. Such injuries would easily be overlooked or forgotten, and this would account for the frequent absence of a history of trauma of such violence as would ordinarily be considered necessary to produce such changes.

Primary necrosis of the portion which becomes detached has been shown not to occur in at least a certain percentage of cases, and portions killed experimentally by radium do not slough into the joint. Arterial embolism, either fatty or bacterial, cannot be accepted as the cause, for there is no plausible reason why it should be limited to the particular regions of the ends of the bones from which the loose bodies spring. There has been no definite pathological evidence presented in support of embolism. Constitutional disturbance of the bones may play a rôle, but not enough clinical or pathologic data are at hand to warrant one in classifying the zones of separation as identical with the clefts of Looser which form in the shafts in such diseases as late rickets and osteomalacia. No inflammatory socalled changes have been observed in loose body, and osteochondritis dissecans has never been observed during the stage of separation of a fragment consisting of bone and cartilage.

Phenoltetrachlorphthalein in the Study of Liver Function.—W. W. Boardman and G. D. Schoonmaker (*American Journal of the Medical Sciences*, November, 1924) present the following conclusions: 1. In phenoltetrachlorphthalein we have a valuable means of studying the functional activity of the liver. 2. The findings by the duodenal tube method and the Rosenthal method are apparently of equal value and significance. 3. Therefore the choice of method ordinarily rests with the individual preference of the investigator, except in cases of common duct obstruction, or when for one reason or another the passage of the tube is contraindicated or impossible. Our own preference is for the duodenal tube method whenever possible, because of the natural objection on the part of the patient to the injection of large amounts of highly colored material intravenously and because of the danger of induration and thrombosis with these large injections which are necessary in the Rosenthal method. 4. With the duodenal tube method we would recommend the adoption of the fifty mg. dose as the standard, because there is no apparent advantage in the larger doses. 5. Because of the impossibility of collecting all the bile excreted over a given period quantitative estimations by the duodenal tube method are of no value. 6. With one hundred and fifty mg. of the dye an initial appearance time of eleven minutes or over and a maximum appearance time of fourteen minutes or over, would seem to indicate liver disturbance. In normal cases the time between the initial and maximum appearance of the dye rarely exceeds three minutes. In pathological cases this time is frequently but not uniformly increased. It is our impression that the maximum appearance time may occasionally be influenced by the factor of dilution by the gastric contents and, therefore, be less reliable than the initial appearance time.

If You Use It Once--

you will readily understand why so many physicians in choosing a reconstructive tonic invariably order or prescribe

Gray's Glycerine Tonic Comp.

(*Formula Dr. John P. Gray*)

Its results will not be uncertain nor delayed, and like so many other practitioners, you will be impressed with their prompt, positive and permanent character. Best of all, your patients will be as quick to note its effects and appreciate the substantial nature of the benefits they will uniformly obtain.

The fact that Gray's Glycerine Tonic has been serving the profession for over a third of a century and that every year witnesses its increased use by discriminating medical men, "tells its own story".

Valentine's Meat-Juice

The **Power** of **Valentine's Meat-Juice** in **Quieting** the **Irritable Stomach, Aiding** the **Digestion, Restoring** the **Appetite** and **Sustaining** and **Strengthening** has been demonstrated by many **Medical Men** in the treatment of

Anaemia, Exhaustion *and* Debility.

Dr. R. Sarandeses, *Physician to the Provincial Hospital Oviedo, Spain:* "I had occasion to use VALENTINE'S MEAT-JUICE on a member of my own family and with excellent results. It is most agreeable to the sick and well, is easily prepared and administered, and for the young anæmic constitutes a superior remedy."

Dr. Lenoble, *Surgeon in Chief, Military Ward of the Hospital D'Argentan, Argentan, France:* "The powerful reconstituent, VALENTINE'S MEAT-JUICE, brought about a great improvement in the condition of the sick and wounded, whose long stay in the trenches had made them particularly anæmic."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
Richmond, Virginia, U. S. A.

S 13

VALENTINE'S PREPARATION
NUTRIO PERFECTA
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

The Speed of Ambulances.—Traffic everywhere gives way, as it should, to the motor ambulance. But that is no justification for the speed at which these ambulances are occasionally driven. In the capital cities of both England and Ireland the efficiency of the ambulance service is very high. No time is lost in despatch, and the handling of patients is both gentle and free from unnecessary delay. Why therefore any hurry on the road? In a drive of a few miles through the city the careful driver is seldom more than a minute or two slower than the rash one, and despite popular belief to the contrary these few minutes are very seldom of importance to a patient. We feel that the drivers of our excellent ambulances should be in this respect superior to human weaknesses. It is a failing common to many motor drivers that they imagine it is possible to gain time by hurrying through crowded streets. On country roads few accidents are due to speed alone without carelessness, but many city accidents are due solely to the attempt of drivers to go a little faster than the stream of traffic.—*Medical Press and Circular,* August 3, 1925.

Nails! Nails! Nails!—In analyzing reports of accidents, ones attention is immediately arrested by the excessive number of casualties due to nails as compared to those due to any other particular cause. One day's mail at the New York City office of the State Department of Labor contains the first report of an average of thirty accidents from nails. This average was gained through noting the reports for five different days over a period of one month. Out of 150 such reports, 37 accidents were reported as infections with loss of time; 45 showed lost time and 68 no lost time. Since in many cases the first report is mailed shortly after the accident, it is certain that a percentage of the 68 no lost time accidents would subsequently show some loss of time. Using thirty accidents a day as a basis of reckoning, we have 9,000 for a 300-day year for the Metropolitan section alone. Should this be equalled by the balance of the State, there would be 18,000 a year. Add to this figure the accidents that cause no loss of time which may not be reported and the exposure to the nail hazard commences to show its seriousness. One thousand three hundred and thirty-eight accidents due to nails were compensated in one year in New York State.

It can well be said that nails "attack every part of the human body." The reports state, in part: "Stepped on nail in floor," "stepped on nail in board on floor," "nail in guard rail tore his scalp," "nail flew from box while loading truck, infected wound on nose," "while stuffing paper in barrel, punctured arm on a nail," "nail in bench tore leg," "rolling barrel, a nail caught tip of little finger on right hand pulling off part of the nail and tip of little finger," "while packing a case the cover, which was full of nails, fell down, the nails going into his hand," "fell down and a nail punctured stomach," "stick with a large protruding nail fell onto hand," "driving a nail it flew into face cutting cheek," etc., etc.—Robert B. Northrup, *Industrial Hygiene Bulletin,* September, 1925.

Antievolution Movement Ignored by Publishers.—Evolution stays in most schoolbooks. That at least seems to be the verdict of American publishers. In response to an inquiry from Science Service, addressed to thirty-five publishing firms, who among them supply the great bulk of the books used in American schools and colleges, thirty-three answered that they were making no changes in their texts to meet the demands of the antievolutionists. One large firm replied, "We are not at present prepared to make any definite statement," and one did not answer at all. None seemed willing to state that any changes were being made. One concern stated that in a new work intended for high school use the matter was "tactfully handled," but that evolution remained in none the less. Others were more emphatic; answers like "Certainly not!" and "Antievolution has no standing with this firm" were characteristic. A vexed question has been the possibility of getting out modifications of standard texts for use in regions where the antievolution feeling is strong. For the most part, the publishers answer with some variant of the statement of one of the largest producers of textbooks for secondary schools: "We are not preparing any special editions of our books for use in states where evolution teaching is prohibited or discouraged."

Insanity.—Many instances could be recalled of persons who at one period have been stigmatized as insane for holding opinions and advocating methods which in after years have gained for others the approbation of the learned. Aubrey tells us that Harvey was considered a madman by many of his contemporaries for publishing his theory of the circulation of the blood, and that he lost much practice in consequence. At the trial of Dr. John Elliott for the murder of Miss Boydell in 1787 the plea of insanity was raised on the ground that he had published some opinions on solar light which induced the belief that he was laboring under mental derangement. These actual observations were afterwards affirmed by Herschel, who received the homage of the scientific world for doing so. Emanuel Swedenborg, in the *Dædalus Hyperboreus,* which was first published in 1716, briefly described a flying machine consisting of a light frame covered with strong canvas, provided with two large oars or wings moving on a horizontal axis, but arranged so that the upstroke meets with no resistance while the downstroke provides the lifting power. "It seems easier," he says, "to talk of such a machine than to put it into actuality; for it requires greater force and less weight than exists in the human body. The science of mechanics might perhaps suggest a means, viz., a strong spiral spring." He knew that his machine would not fly, but he made the suggestion as a start, confident that the problem would be solved in time. That was given to the world in 1716. One hundred and fifty years later (about 1860) the late Dr. Henry Maudsley adduced Swedenborg's anticipations of the flying machine as one of the evidences of his mental aberration. There is much in Swedenborg's philosophy which deserves the consideration of the scientific student. We refer to the inquiry and investigations contained in the *Animal Kingdom,* which was published just before his so-called "Illumination."—*Medical Press and Circular,* July 22, 1925.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

The Retention of Intestinal Poisons

is now recognized as the chief factor in the causation or aggravation of many acute and chronic ills. The immediate removal of these poisons is always imperative, and to accomplish this there is no remedy more effective than AGAROL COMP.—a delightfully palatable and well balanced preparation of mineral oil, agar-agar and phenolphthalein.

AGAROL COMP. not only assures prompt and satisfactory elimination, with gratifying relief from the influence of retained poisons, but presents the further advantage of promoting permanent restoration of normal bowel function.

Thus its ingredients mix thoroughly with the bowel contents—the oil softening and lubricating the fecal mass, the agar-agar retaining moisture and increasing its bulk, while the phenolphthalein furnishes the initial impulse that starts the peristaltic wave.

Not only will satisfactory elimination be accomplished without delay, but as a result of the continued effect of Agarol Comp. on the secretory and mechanical processes of the bowel, regular evacuations will follow naturally without requiring the aid of any further medication.

AGAROL is the *original* Mineral Oil—Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances; not habit forming.

Bottle and literature mailed gratis, upon request.

Poisoned Through the Skin.—Most of us are inclined to think that the skin is a great protection against absorption of poisonous substances. Surgeons, for example, often scrub their hands with bichloride of mercury solutions and put on rubber gloves without bothering to dry the hands. Bichloride poisoning might be acquired in this way. Other poisons are sometimes absorbed through the skin. For instance, a Philadelphia painter spilled a large quantity of wood alcohol over his clothing by accident, and became blind. The doctors say the wood alcohol went through the skin into the blood, and was carried to the optic nerve, and so did the damage.

West Virginia Has Injunction and Abatement Law.—The West Virginia State Department of Health is making plans for the enforcement of the Injunction and Abatement Law enacted by the State legislature and effective July 15. The law provides for the closing as a nuisance of any place used for purposes of prostitution, assignation, or lewdness. A suit in equity may be brought by the attorney general of the State or the prosecuting attorney of the county wherein the nuisance exists. Should public officials fail to enforce the law, a private citizen, resident, or taxpayer may bring in the name of the State a suit in equity to close by injunction a house of prostitution, or one used for purposes of assignation, or lewdness. The law permits the abatement of such a nuisance and perpetually enjoining any person from further maintenance thereof.

According to the United States Public Health Service, there are still ten States without legislation for this purpose. Texas has a law without the abatement feature; the New Jersey law was declared unconstitutional in 1919; and the Maryland law became ineffective two years after the World War

Canal Zone Rain Fall Record for the Year 1924.—The Panama Canal's hydrographic records for the year 1924 show that the Chagres river watershed off flow was but ninety-three per cent. of normal and but eight per cent. more than the normal yearly amount of water come into Gatun lake. In round numbers eight per cent. of this Gatun lake inflow evaporated; slightly more than twice that much was used in locking ships; twenty per cent., or about three per cent. more than that used for locking ships, passed through the hydroelectric turbines to make power at the spillway; less than one per cent. escaped as leakage or was consumed as water through the mains and fifty-five per cent. was washed over Gatun spillway.

A rainfall oddity of the year was that in August the Pacific side had more rainfall than the Atlantic side, being as much above its usual habits as was the Colon side below.

The date of the initiation of the present dry season appears to be about December 12th. This was evidenced by the beginning of the northerly trade winds and the change in humidity. However repeated cold northern storms gave intermittent showers and cloudy weather on the Pacific side, making a transition period up to January 12th. The generally favorable condition for dry season water supply need for much Miraflores made power, unlikely. In fact, the January Gatun lake inflow was a little more than normal.

Syphilis in Porto Rico.—The newly established *Porto Rico Health Review,* issued by the Department of Health, makes the following comments on syphilis:

"Although we have no exact knowledge of how much syphilis there really is in Porto Rico * * * we feel sure that it ranks high, if not the highest among the causes of death. The advanced symptoms of this disease are classified by the general terms of apoplexy, Bright's disease, aortic insufficiency, stenosis, etc. * * *. At the prenatal clinics we daily find an alarming proportion of syphilitic mothers * * *. It is not surprising that we still have an infant mortality of 128 per thousand or twenty-five per cent. of all deaths. Statistics show that at least seventy-five per cent. of syphilitic children die under the first year of age. Syphilis is a problem of public health rather than a matter of morals; it is much more controllable than tuberculosis * * * and inasmuch as its removal from the Island will rid us of this plague, all efforts and expenses for such a noble end are justified."

Care of Dependent Children.—"There is no place like home" for children, according to the Children's Bureau of the U. S. Department of Labor. If institutional care is necessary, however, the Bureau urges that the institutions be as homelike as possible. Such a children's institution is illustrated by a new model exhibited by the Bureau at Washington during the recent meeting of the International Council of Women.

This model shows a miniature "cottage institution," pleasantly located in the midst of a rolling countryside boasting a brook or small river, woods and open meadows—ideal surroundings for growing children. A paved road and electric trolley connect the institution with a nearby town or city, the outskirts of which are represented in the model by miniature houses, churches, schools, stores, and even a moving picture theater.

The institution itself as shown in the model is far different from the conventional idea of an "orphan asylum." Eight small cottages, looking like very attractive bungalows, each surrounded by shady lawn, provide living quarters for approximately 100 children. Each cottage would, in real life, accommodate 12 children, a house mother and her assistant. The children of each house would have their own dining-room and living room, and the whole atmosphere would be that of a big family. Conveniently near all the cottages is a playground with all kinds of apparatus, a gymnasium, a baseball diamond, a swimming pool, and individual gardens for each child, affording ample facilities for recreation and exercise. Other buildings included in the institution are an administration building, a reception and isolation cottage where new arrivals are housed, a superintendent's house, a farmer's cottage, a big barn, a central power house, a garage, and a central laundry. The children's cottages are all one-story. The general buildings are in most cases two stories. There is no school or church connected with the institution because it is considered desirable for the children to attend the town churches and the public school, thus making normal contacts with the community.

NEW YORK

Syphilitic Insane Cost New York $580,762 Annually.—The State Hospital Commission reports that for the year ending June 30, 1924, 911 of the insane people admitted to institutions owed their insanity to syphilis. The syphilitic insane stay in a State institution an average of one and one-half years. The cost per year for each patient is $425 which makes an average total cost of $637.50 for each syphilitic insane person. This makes an estimated cost for care of the 911 syphilitic insane admitted during the year $580,762. The care of these venereally infected persons is a heavy burden on the taxpayers.

Tuition Fees and Scholarships in Medical Schools.—As shown in the statistics published this week, the average tuition fee for each student is now $236, or just double what it was in 1910. In 1921 the average fee paid by each student was $185, in contrast with which the actual cost of his medical training was $655—more than three times what he paid in fees. With the greatly increased equipment in our medical schools, the larger number of salaried expert teachers, and other expensive developments, the average cost per student is now many times greater than it was in 1910. In that year several medical schools reported that all costs were paid from students' fees, and some were said to have had a surplus remaining. Because of the greatly improved instruction, students who can afford to do so should be expected to pay at least a fair proportion of the cost, and a reasonable increase in tuition fees was justifiable. It has been generally recognized that the full cost of maintaining the modern medical school cannot be met from students' fees, so that additional funds are now provided from state aid or private endowment. Recognizing the desirability of financing some students who cannot afford to pay tuition fees, about fifty medical schools have provided, in the aggregate, about 550 scholarships, and thirty or more have set aside generous loan funds. Nevertheless, with the increasing charges for tuition, a larger provision of such aids is needed. They are especially important at this time, since the severity of the modern medical curriculum makes it more difficult for a student to earn money during his medical course. Reports indicate that many students even now earn a major part of their expenses at the same time they carry their medical studies. It is a question, however, whether the money so earned is not at the expense of much valuable experience which the student otherwise might have obtained. It is during the student's medical course, while he is under able instructors, that he has the best opportunity of his lifetime to study and observe patients in both dispensary and hospital. In order to make the best use of this opportunity, it would be better to borrow money with which to meet his expenses, or to have the advantage of a free scholarship. For those who have money to give, therefore, it would be hard to find a more worthy object than in the endowment of more of these scholarships. In the granting of the scholarships, proper safeguards should be established so that the chief object for which they are established, the helping of those who are really worthy of financial aid, may not be defeated.—*Journal of the American Medical Association,* August 22, 1925.

When You Prescribe

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

and your prescription is filled by some cheap, worthless substitute which some druggists buy in bulk, your efforts are defeated and your patient's condition is jeopardized. You owe it to yourself as well as to your patients to make sure that they get

The Original "Gray's"

which has 35 years of faithful service to the medical profession as its guarantee of

1. Highest Quality of Its Ingredients
2. Painstaking Care and Skill in Its Compounding
3. Uniformity and Integrity of Character
4. Maximum Therapeutic Efficiency.

There is only one Gray's Glycerine Tonic Comp. Insure your results and safeguard your patients by writing your prescription as follows—

℞ Grays Glycerine Tonic Comp. (P. F. Co.)

THE PURDUE FREDERICK CO. 135 Christopher St., New York City

Valentine's Meat-Juice

For **Quieting** the **Irritable Stomach** in **Pregnancy**, for **Rapidly Restoring** the **Vital Forces** in **Hemorrhage**, for **Sustaining** and **Strengthening** in **Long** and **Exhausting Labor**, **Valentine's Meat-Juice** is extensively employed in

Obstetrical Practice.

Dr. E. Duloroy, *Physician Accoucher to the International Hospital, Paris, France:* "A young accouchée, in a very weak condition and suffering from stomach trouble, could retain no food, but was able to assimilate VALENTINE'S MEAT-JUICE given at first in small doses. An improvement was quickly visible, the patient recovered her strength and is today in good health."

Dr. Javier Ortis y Ferrer, *Physician to the Municipal Charity of Madrid, Spain:* "VALENTINE'S MEAT-JUICE has given the happiest results in cases of debility and in the asthenia produced by operations of confinements. In some cases of Tuberculosis it restored exhausted strength, and in every case where organic exhaustion manifested itself as an effect of disease."

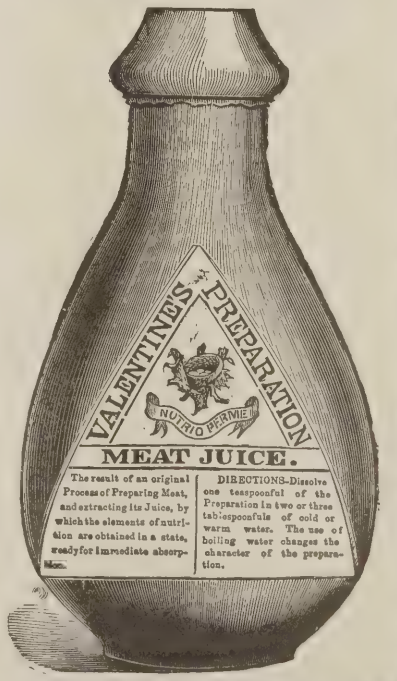
Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

Richmond, Virginia, U. S. A.

S 130



VALENTINE'S PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Occupational Diseases of Seamen.—Dr. H. Ruge, Surgeon Lieut.-Commander in the German Navy, in some interesting articles published in the *Marine Rundschau,* observes that when diseases of seamen came prominently into notice in the age of the great voyages of discovery the first and worst was scurvy. Next in importance were the infective diseases: Typhus (ship fever), typhoid, dysentery, and in the tropics yellow fever and malaria. The number of sick was almost incredible in these early expeditions. In 1757 a French expedition, as it sailed, sent four hundred typhus cases ashore at Brest from two of its ships. A thousand were landed at Louisburg on arrival, survivors were reembarked in autumn, and when the ships reached Brest there were four thousand sick in the fleet, while hundreds had died during the passage. Hosier in 1726, off Colon, lost his personnel twice over from yellow fever.

Little was known definitely about prevention, but Cook (1772-5) and La Perouse (1875-8) had hardly a man sick in their voyages. The food was unbelievably bad; the water was no better. It was not till 1815 that iron tanks began to replace the old decaying wooden casks. To make the dirty, stinking water tolerable it was mixed with rum, of which each man was given five ounces daily. Thereon alcoholism began to rage. Rouppe (1764) calls delirium tremens the characteristic disease of seamen, but improvement set in in the latter half of the century, and the disease is now rare.

Dr. Ruge classifies the sickness of the modern German Navy in four main groups: Chills, mechanical injuries, inflammations of connective tissue, and venereal disease. Under "chills" are included tonsillitis, sore throat, bronchial catarrh, pleurisy, acute catarrhal, gastric and intestinal attacks, and rheumatism of muscles or joints. Chills are more common afloat than ashore (as seventy-five to sixty-five), more frequent in iron than in wooden ships (as three to two in 1893-7), and it is the engine room, or rather the stokehold, staff that suffer most, and he comments that these men should always wear jerseys when on deck in cold weather; steam heating of the ship also lessens risk. Mechanical injuries cause much loss of time. They are more frequent and more dangerous in sailing ships.

The mortality of accidents in sailing ships is thirty per cent.; in steamships it is only five per cent. But most accidents nowadays occur about the guns, and sailors are the victims; there are few accidents in the engine room. Recruits and men new to the ship suffer most, and accidents are more frequent on Mondays, lessening as the week goes on. This is due to unwisely spent leave at weekends, when, too, venereal disease is most often acquired. Eighty-five per cent. of accidents occur on duty. Many might be prevented by improved construction of ships, but accidents there will always be where people are working hard. Men in ships are fortunate in having a doctor at hand when they are injured, so that wounds need not become septic. Boils cause much loss of service; they are generally on the arms, and attack sailors more than stokers. They are at their maximum in summer but have a second maximum in autumn, when the recruits join. The recruits are very susceptible, probably because they are constipated. Cleanliness is the best protection against boils, and once they have a hold on the ship, the ship should be disinfected. Three quarters of the venereal infections are contracted by men under the influence of alcohol. At Hamburg, Noche found seven thousand cases of venereal disease in three years aboard ships entering the port. The East Asiatic Squadron has had one third of its force at one time under treatment.

Sailors suffer much from syphilis, and the worst infected women are at the ports. Unlike alcoholism, venereal disease has decreased little since the war. The men in the German Navy are warned, preventives are always available for them; the merchant seaman is less protected. Dr. Ruge's article deals interestingly with a subject too little discussed. —*Lancet,* September 5, 1925.

Vermouth.—Vermouth wine has recently become a common article of commerce in this country, although it has been popular for many years on the Continent as a stimulant and an aperative, says the *British Medical Journal,* August 29, 1925. Its use appears to be extending, and it is taken now not only with soda as a mild alcoholic beverage, but forms the basis of most cocktails. Recipes for its preparation are numerous, but the following will serve as a sample: "Wormwood, 4 oz.; tansy, 4 oz.; gentian, 2 oz.; angelica root, 2 oz.; blessed thistle, 4 oz.; calamus aromaticus, 4 oz.; elecampane root, 4 oz.; centaury leaves, 4 oz.; germander leaves, 4 oz.; nutmegs, 15; oranges sliced, 6; alcohol of 85°, 9 pints; sweet white wine, 20 gals.; macerate fifteen days and filter." It will be seen from this that several of the plants contain principles which excite the cerebral cortex; especially is this the case with wormwood and tansy, which contain a principle, thujone, which is isomeric with camphor and which causes epileptiform convulsions in sufficiently large doses just as camphor does.

It is for this reason that France has forbidden the drink absinthe, which is made largely from wormwood and contains a varying amount of thujone. Overindulgence in absinthe induces sleeplessness, a general condition of unrest, and sometimes vomiting. Later vertigo and tremors, especially of the head and tongue, are a marked feature, culminating in epileptiform convulsions in which consciousness is usually lost and clonic convulsions occur. The fits recur at short intervals. Recovery is complete if the habit is broken in the early stages. Besides wormwood and tansy, several other essential oils excite the cerebrum, especially nutmeg, and from time to time cases of convulsions following the eating of nutmegs have been recorded.

Vermouth is thus a mild alcoholic beverage, containing about three quarters as much alcohol as is present in sherry, but its action is fortified by thujone and other principles from essential oils, and it is no doubt these substances which induce the exhilarating effects of the beverage. It should not, however, be placed in the same category as absinthe, although both contain the same principles; the relationship between these two drinks may be compared with that between a light wine and a spirit.

THE VALUABLE MEDICINAL PROPERTIES

of Dr. Siegert's

ANGOSTURA BITTERS

(Elix. Ang. Amari Sgt.)

are established by the testimony of medical practice throughout the world for three generations. It has wide scope as a flavoring agent in prescriptions, and also as a tonic and direct stimulant of appetite and metabolism. For a complimentary sample and particulars write to

SOLOSAN COMPANY, Inc., Morristown, N. J.

Kentucky Is Appointing Cooperative Clinicians.—The Kentucky State Board of Health is appointing cooperative clinicians throughout the State for venereal disease work. Members of the state and county medical societies who are listed by the County Health Officer as particularly interested in venereal diseases, are eligible for these appointments. The arrangement provides for the treatment of indigent patients and for the enlightenment of the community in the venereal disease problem. The patient helps to defray the cost of drugs and of other materials by contributing according to his ability, but not to exceed two dollars. If the patient is able to pay more than two dollars, he automatically becomes a private patient. The Kentucky State Board of Health pays half of the cost of the drugs used in the treatment of indigent patients, the clinician paying the other half out of the contributions made by the patients. The State Board of Health makes available to clinicians at cost, drugs and materials to be used exclusively in the treatment of indigent patients.

Each clinician is supplied with *Venereal Disease Information* and *Social Pathology*, two periodicals issued by the United States Public Health Service for use in its cooperative work with State departments of health. The Hot Springs Venereal Disease Clinic is also open to clinicians who may desire to become more fully acquainted with the various phases of venereal disease control. Strip film views of syphilis and of skin diseases simulating syphilis will also be available to the State Board of Health for use in interesting physicians and medical students in fortifying themselves in the detection and treatment of venereal disases and in actively cooperating with the health authorities. These films have been specially prepared by the United States Public Health Service from original photographs and negatives made available through the generosity and cooperative spirit of a number of syphilologists and dermatologists who agree with the health authorities that effective venereal disease control depends upon the active cooperation of the physicians and health departments. A representative of the United States Public Health Service is cooperating with the Kentucky State Board of Health in the furtherance of this venereal disease activity through public education regarding the nature of these diseases and the value of therapeutic and prophylactic measures.

The Prevalence of Cancer.—The collection of statistical information concerning the prevalence of cancer is one of the two principal objects of the American Society for the Control of Cancer as stated in its certificate of incorporation, and to this subject the society has given much attention ever since it was created a dozen years ago. In view of this fact and of the many uses to which statistical data as to the mortality from cancer may be put in the educational campaign which the society is leading, the following information is of much value.

In considering these figures it will be well to remember that they represent official death rates as compiled by the Bureau of the Census from copies of the original death certificates and supplied by the several states in which the deaths occurred, and estimates of population based on the preceding census, due allowance being taken into consideration for the increase since the last enumeration was made.

A death rate is really the number of recorded deaths which have occurred during the year compared with the population on a certain day of the year and is usually expressed as so many deaths in 100,000 of population if for a particular disease, or so many in 1,000 if all causes of death are included.

Cancer is nowhere a reportable disease in the United States and the prevalence of cancer can only be estimated from the death returns. This is hardly a satisfactory method of arriving at it, inasmuch as the duration of the disease varies considerably, being taken by some authorities to average two years and by others three years before death occurs. With an illness of such long duration it is obvious that many persons who have cancer, and would assuredly die of it in time, must die of other and more immediately fatal diseases, as pneumonia, for example, and so escape being recorded as dying of cancer. This tends to make the cancer death rate lower than it otherwise would be and causes the prevalence of cancer to appear less than it really is.

There is a factor which is more potent than all others put together in tending to make the prevalence of cancer seem less than it actually is, and this is the incompleteness of the original returns. More people die of cancer than are so recorded, the reasons for the omission from the records being many. Chief among them is the fact that many cases are not correctly diagnosed, even when they end fatally. In hospitals where autopsies are regularly performed this error has been found to be as high as thirty per cent. If the death rate is too low the prevalence which is based upon the rate must be too low also. All things considered, and in the absence of better figures, it appears not an exaggeration to assume that the number of cases of cancer which exist at any place at any time is about three times the number of deaths which occur there in the course of a year. This means that in that part of the United States which is situated on the North American continent fully 300,000 persons are suffering from cancer at the present time.

Cancer Clinics.—In the July *Bulletin* of the American Society for the Control of Cancer appears the following list of important permanent cancer clinics in the United States:

The Huntington Memorial Hospital, Boston, Massachusetts.

The New York State Institute for Malignant Disease, Buffalo, New York.

The Barnard Free Skin and Cancer Hospital, St. Louis, Missouri.

The Columbus Cancer Clinic, Columbus, Ohio.

The Blodgett Memorial Hospital, Grand Rapids, Michigan.

The Albert Steiner Ward for Cancer and Allied Diseases, Atlanta, Georgia.

The Todd Memorial Clinic and the Cancer Institute of the Hospital of the University of Minnesota, Minneapolis, Minnesota.

The Memorial Hospital, the New York Skin and Cancer Hospital, and the New York City Cancer Institute, all in New York City.

The American Oncologic Hospital and the Philadelphia General Hospital, Philadelphia, Pennsylvania.

The Pittsburgh Skin and Cancer Foundation, Pittsburgh, Pennsylvania.

The Rochester Clinic of the New York State Branch of the American Society for the Control of Cancer, Rochester, New York.

The cancer clinic of the Women's Welfare Association, Washington, D. C.

PARATHYRIN

A Solution for Intramuscular or Intravenous Injection Containing the Active Hormones of the Parathyroid Bodies

Parathyrin is used in the treatment of tetany, paralysis agitans, chorea and other conditions associated with a functionally deficient calcium metabolism such as tuberculosis, osteomalacia, varicose and indolent ulcers.

It has also been used experimentally in certain forms of deranged fat metabolism; in conjunction with insulin in coma of diabetic origin, as well as most convulsive states and in cases of diabetes showing acetonuria.

Ordinarily two doses each week are quite sufficient, but in extreme cases the doses of 1 cc may be given daily or on alternate days for several doses.

The same preparation in triple strength is likewise available for the unusual cases, but the single strength solution is supplied on all unspecified orders for Parathyrin.

Box of ½ dozen 1 cc. ampoules..... $2.00
Box of 100, 1 cc. ampoules..... 30.00

PARATHYRIN INCREASES BLOOD CALCIUM

A Typical Example of the Effect of Parathyrin When Administered to Normal Rabbits Kept on a Constant Standard Diet.

Each rabbit received three doses of single strength Parathyrin subcutaneously at three-day intervals, and were bled for the second test three days after receiving the last dose.

Rabbit No.	Blood Calcium Before Treatment	Blood Calcium After Treatment	Increase in Blood Calcium	Percentage Increase
1	19.5 mg.	22.4 mg.	2.9 mg.	14.9%
2	18.0 mg.	22.0 mg.	4.0 mg.	22.0%
3	15.5 mg.	19.1 mg.	3.6 mg.	23.0%
4	17.5 mg.	20.9 mg.	3.4 mg.	19.0%

CAPROKOL

(HEXYLRESORCINOL S & D.)

$C_6H_3(OH)_2C_6H_{13}$

Indicated in the treatment of infections of the urinary tract.
Approximately 45 times the germicidal power of Phenol.
Non-toxic in therapeutic doses.
Renders the urine a germicidal solution.

FOR ADULTS:—Soluble Elastic Capsules CAPROKOL, (Hexylresorcinol S & D.). Supplied in prescription boxes of 100. Each capsule contains 0.15 gram CAPROKOL, (Hexylresorcinol S & D.) in a 25% solution in Olive Oil.

FOR CHILDREN:—Solution CAPROKOL, (Hexylresorcinol S & D.). Supplied in four-ounce prescription bottles. Each teaspoonful contains 0.1 gram CAPROKOL, (Hexylresorcinol S & D.) in a 2 1-2% solution in Olive Oil.

The Beauty of the Hair.—Taste in women and imagination in artists have cultivated by prodigious invention this domain which would seem to be so limited. I will not retrace the history of the coiffure, for I could only quote from books well known facts. Moreover, it is there in entirety, this history, in statues, paintings, engravings in our museums. When you see them, notice the innumerable variations in their coiffures. This entertaining study is the basis of modern styles, and perhaps you may discover some ancient arrangement that will suit you to perfection. Look for instance at the first bust at the left of the entrance to the Louvre. It is of Poppea, wife of Nero. Her hair is waved as though by Marcel. How many women and hairdressers have passed before it without even guessing at its remarkable revival in our day and the fortune awaiting him who revived it?

Fashion has lost its tyrannical character of other times, when it was necessary to follow the court. Today at a reception, at a "first night" at the opera, in the theatre, a mere glance reveals fluffy hair, hair braided and coiled, some coiffures simple, others ornamented with magnificent combs, many bobbed heads, curled or waved. There is not a style; there are ten, each justified by the wearers who know it is becoming to them and with no attempt to follow rivals. Freedom is absolute. If fashion is lost, the variety which reigns has also its charm; each woman strives for the arrangement which makes her most beautiful.

Before making a choice, consult the mirror and consider most carefully. The hair is really the frame to surround the beauty of the face. Its quantity, its style, its arrangement should be perfectly adapted to the countenance. There should be as many different arrangements as there are faces. A *coiffeur* is an architect whose duty it is to complete an edifice three fourths of which is already constructed."—Translated from *Æsculape,* and quoted from *La Beauté de la Chevelure,* by Dr. Paul Alexandre, Paris, 1924.

The Gauging of Character of Children.—School children, big and little, can be graded, and should be graded as far as possible, according to their moral worth. This is no easy undertaking. Indeed, it needs a special type of genius to divine character, and most of those who have the care of our youth, parents as well as school teachers, are sad blunderers in this respect.

It needs little skill to pick out the downright moral degenerate, the unmistakably callous and incorrigible pupil, but it may happen that those who gain the highest marks for good character are morally inferior to those who are accounted downright bad; the good boy who works hard and never breaks the rules of the school may be a mean, selfish prig, while the boy who neglects his work and who is always getting into scrapes may have a kind and generous nature, only needing the right kind of handling to bring it out.

While the undiscriminating teacher is in danger of misjudging this type of character, there is a class of moral degenerate which no sane person can well fail to discover. These may be grouped under two categories—those who are intellectually normal, or supernormal (the Mephistophelian type) and those who are intellectually defective.

Most of the elementary London Board Schools have an A side for the more intelligent children, and a B side for the duller ones who are given mainly hand work such as needlework and cooking. These are termed backward children, and are distinguished from those who are definitely deficient mentally. For these special schools are provided, just as they are provided for those who are crippled, deaf and dumb, and even for sufferers from lupus. The A side children are much more amenable morally than those of the B side. These are from the moral viewpoint definitely below the marriage standard; indeed, in an ideal state most if not all of them would be debarred from marriage. They are feebly endowed as regards moral responsibility and furnish the largest quota of unmarried mothers.—*Medical Press and Circular,* August 19, 1925.

Yale to Study Mechanics of Walking.—Facts and figures about leverage, stresses, and distribution of weight in the human foot are to be sought by means of specially designed instruments at Yale University. For several hundred thousand years men have been operating that remarkable mechanical device—the human foot—without knowing exactly how the thing worked or what to do when the mechanism failed. X rays and studies of anatomy have helped to reveal the complex structure of the walking apparatus, but experts still differ in their interpretation of how the bones and muscles and tendons are coordinated. Dr. Dudley J. Morton, instructor in surgery at Yale, who is in charge of the foot investigation, says that results of the army examinations during the recent war clearly show the practical value of the proposed research. The usual standard for determining the foot efficiency of the soldiers was the condition of the longitudinal arch. "This method," he says, "led to the rejection of many applicants and drafted men whose feet presented low arches but who had never experienced discomfort even under strenuous activity, because their body weight was properly distributed through their low arched feet. On the other hand, many thousands of accepted recruits who possessed well developed arches were soon assigned to 'development camps' because of foot trouble. These facts testify to the unreliability of the height of the arch as a standard for determining the potential strength and integrity of the feet. The proficiency of the foot depends essentially upon the ratio of weight distribution to the chief bearing points of the feet."—*Science Service.*

The Herpes of Marat.—Amédée Latour recounted once in his *Causeries* for *L'Union Médicale* his interview with Father Souberbielle who was the friend and the physician of Danton, Robespierre and Marat. We know through him that "the friend of the people," being herpethetic, was tormented with an incessant pruritus, which could be allayed only through continual baths. He hardly ever emerged from his bathtub, which was covered with a cloth; only head and arms were free; a board placed across served as a desk. It was in this bathtub that he corrected the proofs of *L'Ami du Peuple,* and that he was assassinated by Charlotte Corday.—Translated from *Æsculape.*

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

G. W. CARNRICK CO.

417-421 Canal Street • • • NEW YORK, N. Y.

The Menace of Animal Diseases from Foreign Countries.—During the past year two significant examples have occurred of the danger and great economic loss which may result from the inroads of foreign pests and of the danger of widespread disaster to some of our great industries. These examples were the outbreak of foot and mouth disease among livestock in Texas and California, and the appearance of the European fowl pest in poultry flocks of this country last December. The method by which the foot and mouth disease outbreak gained entrance has never been determined, but the fowl pest was in all probability introduced through an investigator working on filterable viruses in a large institution in the summer of 1922, according to a recent report from the United States Department of Agriculture. The virus was obtained from the Pasteur Institute of France where the disease exists. The investigator who introduced the virus gave some of it to another investigator, and a second sample was distributed for laboratory investigations. An assistant took some home and inoculated chickens in order to maintain a supply of live virus for continuing investigational work in the fall. Some of the poultry was probably sold to dealers and the infection spread—and so the story goes.

The Department of Agriculture does not permit the importation of animals from countries having destructive animal diseases not present in the United States, for it believes that the security of some of our greatest industries depends upon the observance of all precautions, not only by those engaged in commerce, but by those engaged in scientific work. The report states that only recently there arrived from Africa a scientist who carried with him a sample of hog's blood which, had he lost it in any way, might have proved a greater menace to swine in the United States than hog cholera ever was. The sample of blood was at once burned. "The gentleman from East Africa had the best of intentions. He wished to have the scientists who had been so successful in combating hog cholera in this country work on an unknown disease which was causing great losses to swine breeders in his country. He described it as a disease which is much more contagious than hog cholera and kills the animals in a much shorter time and in much greater numbers. It would indeed have been an effective demonstration of international friendship if the department's scientists had been able to solve the problems of the farmers in East Africa. But the risk taken is much too great. The place to study this unknown enemy is East Africa."

During the preparation of the report a Swiss arrived at the Bureau of Animal Industry carrying a bottle of attenuated virus of foot and mouth disease. He had brought it from his country in order to try it out in this country as a means of fortifying flocks and herds against the diseases by giving them mild cases. He, of course, had to leave the sample at the bureau and it was destroyed.

Other examples could be cited in which dangerous possibilities were involved. The recent Second Deficiency act passed by Congress provides money for carrying on work with the foot and mouth and other disease by our scientists in the countries where they exist regularly, and this must necessarily result in greater safety for ourselves and for our livestock.

If You Use It Once--

you will readily understand why so many physicians in choosing a reconstructive tonic invariably order or prescribe

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

Its results will not be uncertain nor delayed, and like so many other practitioners, you will be impressed with their prompt, positive and permanent character. Best of all, your patients will be as quick to note its effects and appreciate the substantial nature of the benefits they will uniformly obtain.

The fact that Gray's Glycerine Tonic has been serving the profession for over a third of a century and that every year witnesses its increased use by discriminating medical men, "tells its own story".

VALENTINE'S
PREPARATION
NUTRIO PERAMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS–Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

The Duty of the Family Physician.—Dr. D. E. Sullivan, secretary of the New Hampshire Medical Society and a member of the Gorgas Memorial Institute, Chicago, writes as follows concerning the importance of periodical physical examinations.

"For many years there has been a well organized system in the United States to protect public health —that is, the health and lives of citizens as a mass formation. Thereby have been accomplished definite results in some instances, notably the practical elimination of typhoid fever as a menace and the protection of school children through medical supervision and the application of preventive measures. In the meantime, however, the individual has received scant attention and only during a more recent period have his particular requirements claimed the attention of the medical profession. While the need of regular periodical physical examinations is recognized and advocated by all progressive physicians and has been officially urged by the American Medical Association through the House of Delegates, it does not require very close observation to note the indifference of our fellow practitioners to the call.

"State and county societies have evidenced cooperation with the central organization by the adoption of resolutions, naming special committees to carry on the work and devoting space on their programs to its consideration but what, so far, has been the response of the vast majority of the members? Very few of them have heartily recommended it to their families or given the subject anything more than a passing consideration.

"The opportunity is ripe to confine such an important matter to the ranks of family physicians and wrest it from exploitation by commercial institutes. But this will not be accomplished, unless we display more personal, active interest in getting the message to the people. We need to be cooperative, 'to push' the splendid educational work of the Gorgas Memorial Institute, now under way in the newspapers of our country.

"While the more urgent application of the necessity of this work may be of greater vital interest to men and women of midlife, no age or class is exempt. A careful scrutiny of a babe may disclose conditions or apparent tendencies of disease which, recognized in season, will result in a sound mind in a sound body instead of a crippled limb or arrested mental development. The growing child will record defects of eyesight or hearing unrecognized by the parents and by properly applied remedies saved from a life of dependency, and so on through the several decades until its greatest worth is found after middle life. It is our duty to be the leaders in this movement, to enter upon it with well equipped and united ranks, to give proper publicity of its necessity to the people and devote full and sufficient time to every examination.

"Too long has the mind of the medical man been focused on disease principally. Let him now devote special attention to the presumably well. The average person cannot be expected to recognize the indications of developing harmful symptoms of disease. Let our profession resolve to contribute to human progress the best of its resources."

The Country Doctor.—In the opening chapter of his interesting Reminiscences published in the *New York Times,* the late Thomas R. Marshall, Vice-President of the United States, pays a glowing tribute to the country doctor as represented in the person of his father. Mr. Marshall writes:

"I doubt if it be possible for the pen of man really to embalm in words the trials and incidents of such a life. Indeed, it would be almost a useless task to undertake the writing of it, for it is not worth while for one to read that which he cannot visualize with some of his own personal eyesight. . . . And yet I think, if service is to be the true mark of greatness in a people, all these other wonders of a wondrous age and State must pale into insignificance beside the service and sacrifice of the country doctor.

"Each age for itself, and each man for his age. I would not go back to the old times. I recognize the accuracy of the scientific investigation of the present time; I am asking for no more country doctors; but I have taken off my hat in grateful love and veneration for that innumerable company which helped to bring Indiana out of its primeval into its cultural state.

"And yet there is just one regret. It is the regret that with the country doctor has also disappeared the old family physician—the man who knew your peculiarities, your idiosyncrasies and your life. He was as much bound up in your destiny as your minister or your lawyer. He was adviser, counselor, friend. If I could rehabilitate him, put him in every community in America, get him to be my friend, I could be elected to any office within the gift of the people. It is nothing against science; nothing against these specialists; nothing against their accuracy, and it is not regret over the fees that we pay, but I do sometimes long to have an old family doctor that could really find out what is the matter with me without passing me down the line of from fifteen to twenty experts that know about an inch of the human anatomy, and know no more."

Industrial Accidents and Compensation Costs.—In a statistical review of industrial conditions in Pennsylvania by the Department of Labor and Industry, it is stated that more industrial accidents were reported to the Bureau of Workmen's Compensation during the month of June, 1925, than in any previous month of this year. There were 199 fatal industrial accidents reported during June, which record is second only to that of January, when 202 were reported. A classification of the fatalities shows 76 to have been reported by the coal mining industry, 29 by transportation and public utilities and 94 by all other industries.

Of the 1,087 fatal accidents reported for the first six months of 1925, the anthracite coal industry was responsible for 296, transportation and public utilities 169, the bituminous coal industry 167, the metal industries 159 and building and contracting 112. Fatal injuries to State and municipal employees numbered 40 for the six months' period.

There was an increase in practically all of the permanent disability cases during the month of June, especially in the miscellaneous cases and eye losses. The total amount of compensation awarded for this type of injury for the first six months of 1925 is more than $1,451,000.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Education in Safety Methods.—"The man who holds the most important safety job in America, and probably in the world from the viewpoint of the number of employees affected and the money invested, has said that he would rather accept responsibility for accident prevention in a plant that did not have a single mechanical safety device, but where there was the spirit of safety among the workmen and managers, than in a plant where there was every known physical safeguard, but not this spirit of safety."

This is quoted from an article by Arthur Williams, general commercial manager of the New York Edison Company and president of the American Museum of Safety, on Effective Accident Prevention by Educational Methods in the *Nation's Health*. He calls this statement the best commentary on the extent to which education may be relied upon and is demanded for the prevention of industrial as well as of civic accidents. Another indication of the value of education is shown in the present exhibits of the American Museum of Safety, which emphasize educational means for the prevention of accidents in contrast to the machine guards, various safety devices and safety materials of which the exhibits were formerly largely made up. Now photographs, stereopticon slides and other graphic exhibits show the schools for foremen, safety meetings of the workmen, bulletin board posters, safety publications, and other matters.

Professional safety engineers who have watched the development of the accident prevention movement from its infancy say, the writer states, that even today, with the hundreds of ingenious safety devices available, with automatic machines that are almost "fool proof," and with safety incorporated in the design, construction, and installation of industrial equipment, it is possible to prevent only from twenty-five to fifty per cent. of industrial accidents through mechanical means. Prevention of the rest depends upon education in safety, better supervision, and improved morale of employees. This estimate is borne out in an analysis made of some three hundred thousand accidents that occurred over a period of many years in the United States Steel Corporation plants.

The analysis shows that hand labor was responsible for more than forty per cent. of the accidents. The company's safety manager stated that the majority of these accidents could not possibly have been prevented by the use of mechanical safety devices or appliances, but were due to carelessness and the failure of workmen to observe the simple precautions conducive to safety. We know today that carelessness is as much a frame of mind as it is a bodily habit, and we are working on discovering the causes of this frame of mind, and how to change it. Often it is due to lack of confidence in the sincerity of the employer, or failure to understand his motives.

Safety education in the major sense probably means, the writer believes, that development of oneself "so that he is constantly, automatically, subconsciously on guard against accident. Many years of personal safety in the character of the work done in a shop, or the traffic upon the highways, have subordinated or practically eliminated the elemental sense of caution in every human being. In the early days of the republic, everyone was in danger from Indians and wild animals, and therefore everyone was always on guard, and any unusual or unexpected sound, like a rustling twig or crackling stick, brought one to immediate attention, looking for possible danger. Today every industrial activity is accomplished through the aid of high speed and dangerous machinery; a very large percentage of our population lives at great relative heights from the ground; highways, even in the quiet secluded country, are occupied by heavy, high speed traffic, that makes them more dangerous than the usual right of way occupied by a railway. The dangers of the early days of the republic are multiplied a thousand fold on every hand, and we must train ourselves to be constantly on the watch wherever we are—in a power plant, factory, on the highways, or traveling by boat or train."

The article is concluded by a paragraph on the new profession of "safety man," to which there are probably five thousand giving their entire time and work to it as a life profession. "These men should be considered in the highest degree as elements of economy and efficiency in our industrial and commercial life, for in every instance organized safety effort, both in plant equipment and education, pays and pays handsomely."

Infrequency of Cancer Among Primitive Peoples.—Frederick L. Hoffman, LL.D., consulting statistician to the Prudential Insurance Company of America, finds that primitive races are practically free from cancer, appendicitis, diabetes and other diseases suggestive of metabolic disturbances, and he says that it is not easy to exaggerate "the positive evidence of the rarity of cancer occurrence among uncivilized or primitive races."

"Why, for example, should cancer of the breast be practically absent among the women of the Indians of North and South America?" he asks. "Why should this fatal and increasing affliction be ten times more common among the women of Great Britain than among the women of Japan? Until the subject of the rare occurrence of cancer among primitive peoples is thoroughly investigated and understood, little progress towards an improvement in the cancer situation is likely to be made.

"In other words, there is apparently the most urgent need of diverting some of the efforts and means expended upon laboratory research and inquiry towards the infrequency or nonoccurrence of malignant tumors of all kinds among primitive races, and no fields, in this respect, would seem to be of greater promise than a study made among the Indians in North and South America and among the black and mixed blood population of Bermuda, Jamaica and the various other races of Central America and the West Indies. My own investigations among the Indians in North and South America are decidedly suggestive of the conclusion that the essential difference between these races and those who are civilized lies in the matter of diet and the resulting nutritional conditions, favorable or otherwise, as the case may be. If the increasing frequency of cancer is even in part attributable to the dietary habits common to civilized races, it is obviously a matter of first importance that this aspect of the subject should receive more extended and dispassionate consideration."

Automobile Fatalities.—The Department of Commerce announces that reports of automobile fatalities in 1925 have been received from seventy-seven cities of 100,000 population or more. Thirty-nine of these cities show more automobile fatalities in the four week period ending September 12th than in the previous four week period. Norfolk shows no fatalities for the last eight weeks, and in addition the following seven cities show no fatalities for the last four weeks: Albany, Cambridge, Dallas, El Paso, Fall River, Fort Worth and Somerville. Somerville with four deaths holds the record for 1925.

For fifty-seven cities with an aggregate population of twenty-seven million, there were 3,313 automobile fatalities reported in the period January 1st to September 12, 1925, as contrasted with 3,319 such fatalities in the period January 1st to September 30, 1923. Of these 3,313 deaths, 433 were reported in the four week period ending September 12, 1925.

Of the sixty-five cities for which comparisons are possible so far for 1923 and 1925, thirty-five show more automobile fatalities reported in the period January 1st to September 12, 1925, than occurred in the first nine months of 1923.

So far this year New York city has reported 638 automobile fatalities, Chicago 410, Philadelphia 191, Detroit 183, Cleveland and Los Angeles each 154, while for the last four week period the figures are New York city seventy-nine, Chicago sixty-six, Philadelphia eighteen, Detroit twenty-five, Cleveland nineteen, and Los Angeles fifteen.

Research in Mental Hygiene.—A special Subcommittee on Research consisting of Dr. L. Pierce Clark, chairman; Dr. Frankwood E. Williams, Dr. Sanger Brown, Dr. Charles L. Dana, Dr. George H. Kirby, Dr. Thomas W. Salmon, Dr. C. Floyd Haviland, and Mr. Homer Folks, after a careful study of this subject, reported on its conclusions at a special meeting of the committee on May 19th. After full consideration of this report, the following recommendations were adopted by the committee as a program of action in this field:

1. That a suggestion be made to the chairman of the State Hospital Commission, the State Commission for Mental Defectives, and the Director of the Psychiatric Institute, that they appoint an Advisory Committee on Scientific Research in the State Institutions. The opinion was expressed that such a committee containing representatives of various departments of medicine, and the allied fields of biology and anthropology, would aid in further developing the scientific work of the institutions.

2. That consideration be given to amending the Medical Practice Act to make it possible for the State institutions to employ scientific workers from foreign clinics, laboratories, and teaching centres.

3. That the Psychiatric Institute consider placing its teaching functions on a continuing basis, in order to promote the further development of the teaching as well as the research functions of the institute.

4. That the chairman of the State Hospital Commission and the State Commission for Mental Defectives address a letter to the Rockefeller Institute asking the institute's aid in chemical and bacteriological study and research on various aspects of the problem of mental disorders and mental defects, and suggesting definite problems for research and inquiry.

Miscellany.

Coffee Drinking by Children.—Coffee drinking by children has long been regarded with disapproval by pediatrists. There are a number of objections to the practice, among which its harm to the nervous system is important. It is entirely conceivable that the use of caffeine containing beverages by the child will lead to the production of serious nervous defects later in life.

In their recent book, *Safeguarding Children's Nerves* (1924), Walsh and Foote clearly indicate that there is an increasing nervous instability of American people as demonstrated by the failure of many of our troops to withstand the stress and strain of active service. These writers believe that the numerous cases of shell shock which were suffered by many American soldiers in the World War were nothing more than cases of hysteria. It is possible that the early use of coffee has had a contributing part in causing the lack of nervous balance that is exhibited by so many adults in this country.

The drinking of coffee in the United States is steadily increasing, and the average annual consumption now amounts to thirteen pounds or more per capita. No small portion of this coffee is used by children, as shown by a study of the diet of a large number of children of preschool age at Gary, Indiana. This survey was made by the Children's Bureau of the United States Department of Labor. The report mentions that "two thirds of the entire group were found to drink coffee habitually, and forty per cent. to have it more than once a day. Not only so, but in certain of the groups of foreignborn parentage, coffee was drunk by more than ninety per cent. of the children, and three fourths of the Polish group had it two or more times a day."

In 1912, C. K. Taylor, a psychologist, made a study of coffee drinking by school children. He found that out of a group of 464 children, over seventy per cent. of them were coffee drinkers. Moreover, and more important still, he discovered that those children who drank the most coffee received the lowest grades. There is no doubt that coffee drinking is generally deleterious to the nervous system of the child, but the greatest harm done to children by this drink is its replacing milk in the diet. The Gary report, referred to above, states that coffee drinking by children "appears to have been inversely proportional to the use of milk. Not only do the schedules show about the same percentage of children drinking coffee as those lacking milk, but a comparison of coffee drinking by milk groups shows the use of coffee to increase markedly as the amount of milk increases." Commenting upon the disastrous effect of replacing milk by coffee, the report states further: "To leave out milk and substitute coffee plays havoc with any diet, whatever may be its redeeming features."

It is a well known fact that children easily acquire a taste for coffee and are less willing to drink milk after being permitted to use coffee. Miss Lucy H. Gillett, superintendent of the Nutrition Bureau of the New York Association for Improving the Poor, says in this connection that "children should never be given tea or coffee, not even to flavor milk. They will more often like milk if they are not first taught the combination of milk and coffee."

There are two important reasons why coffee should not be given to children; first, it has the harmful effect of crowding milk out of the dietary of the child; second, it is an unneeded stimulant.

In view of the fact that a large number of American children, especially in the industrial classes, are coffee drinkers, the matter is worthy of serious consideration.

First Ascent of Mont Blanc Was Made by a Physician.—After outlining the many previous attempts to scale the inaccessible sides of what was then considered the highest of the Alps, but has now had to take second place, Dr. Louis Masson describes the first successful attempt, which was made by two men, one of them a physician, Dr. Michel Gabriel Paccard, of Chamonix, in company with Jacques Balmat, who was not even a guide but simply a hunter of crystals and of the chamois (*Aesculape,* August, 1925). The latter was twenty-five years old and of most unusual physical strength and energy. He had in his search for crystals many times essayed the ascent of Mont Blanc, but had failed from all sides but the north. On this side he finally succeeded in climbing as far as the great plateau, but had had to descend because of nightfall, but not until after he had made a careful study of the cliffs guarding the remainder of the way, which had never seemed so forbidding. He revealed his discoveries to no one but the physician of the countryside, Dr. Paccard. Paccard was the son of a notary of Chamonix. After studying at Turin and Paris, he had established a practice in the valley. He was then in the prime of life, and, like some of his compatriots, the idea of conquering Mont Blanc obsessed him. He had already made painstaking attempts, and the north side was the only way he, like Balmat, had not tried. Balmat understood the situation. His intention was not only to climb Mont Blanc, but to furnish proof that he had attained the summit. What better witness could he hope for than Dr. Paccard, a witness, who, he was sure, could be depended upon not to rob Balmat of his part of the glory and compensation. So he hastened to consult with him. Bad weather retarded their departure for three weeks. It was not until August 7th that they were able to leave the valley with a prospect of reaching the summit from the north side. Before leaving Balmat had asked a friend to keep watch for their appearance on the snows of the upper slopes. But the progress of the climbers was anxiously followed by the whole village. At four o'clock the next morning the two men reached the glacier. From below, the people followed them anxiously with their glasses, and saw them disappear on the Grand Plateau. The anxious vigil was prolonged throughout the whole day. Suddenly about six thirty in the evening they saw appear simultaneously on the snows of the summit two black dots lost in the immensity of space; it was Balmat and Paccard, who joyfully hailed the whole population of Chamonix. Mont Blanc was conquered. With emotion inexpressible these two men had heard for the first time a silence which, as Javelle says, "had been unbroken since the creation of the earth."

"Diabetes, Diabesan and a Grateful Patient"

Point Pleasant Beach, N. J.,
September 29, 1925.

Dr. Werner.
My dear Friend:—

I can call you friend as "Amicus certus in re incerta cernitur."

When I left the hospital last May after the "Allen Starvation Treatment" I weighed only 106 lbs., very weak and debilitated with glycosuria and glycemia, very much discouraged and melancholy. Dr. Shoub wrote me that he had seen very good results from the "Rational Treatment of Diabetes," by Dr. Werner, President of the Solosan Company of Morristown, N. J. With much misgiving I began your treatment about July last.

I want to congratulate you on my condition. I now weigh 122 lbs., very good color in my face, no sugar in the urine, very little blood sugar, no diacetic acid, no acetone.

I feel much stronger and do not tire easily, as before. I sleep better and not so nervous. I feel better and clinically proven to be better.

A grateful patient,
Rev. Joseph V. Sweeney.

Frequency of Typhoid Fever.—In a comprehensive article on Antityphoid Vaccination, published in the August and September issues of *The World's Health,* Dr. Aimé Gauthier says that until the last third of the nineteenth century typhoid fever was regarded as one of the gravest and most widely distributed diseases of man. Here and there, however, could be found places not invaded by the disease. Such places always possessed excellent drinking water. Little by little the work of the English physicians, Budd and Murchison, the German investigator Pettenkofer, and finally the absolute and precise demonstration of the contagiousness of the disease and its frequent derivation from water made their influence felt. In consequence, many governments and municipalities began the task of arresting typhoid. This task was accomplished by instituting, often at great expense, urban sanitary reforms.

As a rule typhoid fever has diminished or disappeared wherever sanitation of the water supply has been practised. Unfortunately, however, several localities, and even entire countries, do not utilize the advantages of public health measures or have not the necessary funds. In such places the task of controlling typhoid remains wholly unaccomplished and the fever still produces its destructive effects, which are grave in proportion to the degree in which local sanitation is neglected.

Communities exist whose sanitation must always be incomplete. Such is the case with military personnel during wartime, when residence in any place is uncertain. It is for this reason that typhoid, during the wars of the past, has been the constant companion of the soldier, and always one of the most frequent diseases in campaigns. In nearly every instance efforts undertaken with painful labor by the military medical authorities to purify drinking water and to disinfect and destroy human dejecta have encountered unsurmountable obstacles. Since the environment invariably became contaminated, no army prophylaxis founded solely upon sanitation was able to avert epidemics of typhoid fever.

The unfortunate conditions which formerly prevailed were quite reversed during the recent war in which the military medical services, while not neglecting sanitation, were able to utilize a new and very effective weapon—specific vaccination. These general statements must be supported by statistical arguments, which alone are really convincing.

In France, typhoid fever caused, from 1903 to 1920, 161,000 deaths, or about 9,000 deaths annually. The typhoid mortality has diminished materially in France, especially after the period included in the years 1886 and 1901. In 1911 the average mortality of typhoid fever in France was 0.19 per thousand inhabitants. The entire southern part of France—especially the regions bordering upon the Mediterranean—is much affected.

The typhoid situation outside France is here considered only in countries in which typhoid has become relatively rare, either because of climates which favor it little, or on account of special sanitary measures. Before the war the incidence of typhoid fever in Germany, England and especially the Scandinavian countries, was ten to fifteen times less than in France.

In Berlin the typhoid mortality for the period 1871-1885 was 1.0 per thousand inhabitants. For the period 1896-1900, the rate was 0.05 per thousand. Throughout Prussia the typhoid mortality for 1901 was 4,410. For 1909 it was 1,911, the disease being diminished by more than one half. For the whole of Germany the average typhoid mortality was 0.7 per 10,000 inhabitants, while the French rate was 4 per 10,000.

In Stockholm, whose population in 1923 was 424,000, only a few cases of typhoid fever occur every year (eight cases, for example, were observed in 1907) and the typhoid mortality is usually nil.

Radium Destroys Danger of Leprosy Infections.—The successful use of radium in the treatment of leprosy which, it is hoped, will result in the abolishment of the law of segregation that is imposed on those suffering from the dread disease, is reported by M. H. Neil and R. P. Sandidge of the Kalihi Leper Receiving Hospital at Honolulu. So far as can be discovered, this is the first use of radium in the treatment of leprosy, they state.

Following a series of experiments, the surgeons announce that in all cases treated with radium, "the leprous nodules disappeared. It is hoped that, by the use of radium, many lepers may be converted from dangerous carriers, emitting millions of bacilli from their noses, to persons not dangerous to public health and thus no longer in need of segregation."

Experiments with the radium treatment of leprosy have extended over a period of six months, the study being concentrated on the use of the element with especial reference to treatment of leprous lesions of the nose.

Seven patients having nodules in the nose were treated by the insertion of a fifty milligram tube in either nostril, alternating at intervals of from two to three weeks, exposure to the treatment being from one and a half to two and a half hours.

In all cases the nodules disappeared, it is said. In three of the cases the bacteria disappeared from the area under treatment. Other similar cases, not receiving the radium treatment, showed no change in nasal condition.

"It is the intent to extend the scope of this work to determine the permanence of its effects and the effect of clearing up the nose on the patient's general condition," the investigators conclude.—*Science News Letter,* October 17, 1925.

South Carolina Has Effective System of Disease Reporting.—Dr. James A. Hayne, State Health Officer of South Carolina and collaborating epidemiologist of the United States Public Health Service, has instituted a new and decidedly more effective system of disease reporting by physicians. Each week a card is mailed to physicians for the report of the number of cases of diphtheria, gonorrhea, syphilis, malaria, smallpox, tuberculosis, and certain other diseases. The greater effectiveness of this system of reporting is shown by the fact that in the first month of its operation 734 cases of syphilis were reported as against an average of 245 cases for each of the preceding ten months, or three times as many cases as were reported formerly. There is a still higher rate of increase in the number of reported cases of gonorrhea. Over seven times as many cases of this disease were reported under the new system as were reported formerly.

PARATHYRIN

A Solution for Intramuscular or Intravenous Injection Containing the Active Hormones of the Parathyroid Bodies

Parathyrin is used in the treatment of tetany, paralysis agitans, chorea and other conditions associated with a functionally deficient calcium metabolism such as tuberculosis, osteomalacia, varicose and indolent ulcers.

It has also been used experimentally in certain forms of deranged fat metabolism; in conjunction with insulin in coma of diabetic origin, as well as most convulsive states and in cases of diabetes showing acetonuria.

Ordinarily two doses each week are quite sufficient, but in extreme cases the doses of 1 cc may be given daily or on alternate days for several doses.

The same preparation in triple strength is likewise available for the unusual cases, but the single strength solution is supplied on all unspecified orders for Parathyrin.

Box of ½ dozen 1 cc. ampoules.....	$2.00
Box of 100, 1 cc. ampoules.....	30.00

PARATHYRIN INCREASES BLOOD CALCIUM

A Typical Example of the Effect of Parathyrin When Administered to Normal Rabbits Kept on a Constant Standard Diet.

Each rabbit received three doses of single strength Parathyrin subcutaneously at three-day intervals, and were bled for the second test three days after receiving the last dose.

Rabbit No.	Blood Calcium Before Treatment	Blood Calcium After Treatment	Increase in Blood Calcium	Percentage Increase
1	19.5 mg.	22.4 mg.	2.9 mg.	14.9%
2	18.0 mg.	22.0 mg.	4.0 mg.	22.0%
3	15.5 mg.	19.1 mg.	3.6 mg.	23.0%
4	17.5 mg.	20.9 mg.	3.4 mg.	19.0%

CAPROKOL

(HEXYLRESORCINOL S & D.)

$C_6H_3(OH)_2C_6H_{13}$

Indicated in the treatment of infections of the urinary tract.
Approximately 45 times the germicidal power of Phenol.
Non-toxic in therapeutic doses.
Renders the urine a germicidal solution.

FOR ADULTS:—Soluble Elastic Capsules CAPROKOL, (Hexylresorcinol S & D.). Supplied in prescription boxes of 100. Each capsule contains 0.15 gram CAPROKOL, (Hexylresorcinol S & D.) in a 25% solution in Olive Oil.

FOR CHILDREN:—Solution CAPROKOL, (Hexylresorcinol S & D.). Supplied in four-ounce prescription bottles. Each teaspoonful contains 0.1 gram CAPROKOL, (Hexylresorcinol S & D.) in a 2 1-2% solution in Olive Oil.

Diseases Under Investigation at the Rockefeller Institute Hospital.—The following diseases are being studied at the Hospital of the Rockefeller Institute for Medical Research, and patients suffering from them will be admitted to the extent of the hospital facilities.

1. *Nephritis.* Patients suffering from acute nephritis, or from chronic nephritis of either the edematous or nonedematous type. Cases of nephritis in young persons are especially suitable.

2. *Chickenpox.* Children and adults will be admitted to the Isolation Ward after November 1st; those early in the disease are especially desirable.

3. *Acute pulmonary infections, including acute lobar pneumonia.* Persons suffering from atypical forms of acute infection of the respiratory tract as well as patients with acute lobar pneumonia will be admitted. Those with lobar pneumonia should be referred early in the disease in order to permit institution of serum and oxygen treatment as early as possible when they are indicated. A chamber is available in which patients suffering from severe cyanosis may be treated in an atmosphere rich in oxygen.

4. *Rheumatic fever.* Patients should be referred early in the course of the disease, preferably before receiving antirheumatic drugs. Those suffering from one or more of the following manifestations are desired: acute rheumatic polyarthritis; subcutaneous rheumatic nodules; chorea accompanied by polyarthritis or subcutaneous nodules; rheumatic carditis accompanied by polyarthritis or subcutaneous nodules.

5. *Cardiac disease.* In continuing the study of the treatment of chronic heart disease it is planned to admit patients, either young or old, in the more advanced stages of heart disease. While persons with completely irregular pulse and fibrillation of the auricles may still be admitted, those with markedly weakened, but regular hearts are also desired.

Revision of the United States Pharmacopeia.—Robert A. Hatcher, New York (*Journal A. M. A.,* August 1, 1925), reviews the development and scope of the *Pharmacopœia.* He says that the physician must know something of the *Pharmacopœia* in order to avail himself of the advantages that it offers him, but this fact is often ignored, and a great many physicians are lamentably ignorant concerning the work. It is the duty of all teachers who are concerned with therapeutic instruction to assist in familiarizing students with the *Pharmacopœia.* Stress should be placed on the use of official names of drugs and preparations, especially in prescription writing. The *Pharmacopœia* contains a wealth of information for the student of chemistry and medicine and for the prescription writer. This includes suitable abbreviations, solubilities in various vehicles, and doses. The physician will often find it convenient to know in what form suitable for dispensing a given drug is official. This information is given in every case in which a drug enters into an official preparation. The *United States Pharmacopœia* of 1890 contained 994 titles, but the forthcoming revision will have only about two thirds as many, exclusive of those which were admitted as pharmaceutic necessities. It is the purpose of the Committee of Revision to admit only those drugs which are worthy of careful study by the physician, and the *Pharmacopœia* will be increasingly important as a reference work in medical colleges and for the clinician. The *Pharmacopœia* provides rigid standards of purity of drugs for which chemical tests are available. These tests have been studied with extraordinary care, and they suffice to insure a high degree of purity, and no official chemical may be dispensed legally if it contains any harmful impurity. Absolute purity is seldom attainable in practice, and pharmacists and chemists have devoted an enormous amount of time and care to the methods of preparing official chemicals which are free from more than traces of impurities that would be harmful in large amounts. Traces of impurities in drugs are not injurious to the patient. The manufacturers of many proprietary preparations observe no limitations except those that they choose to impose, and these may be changed at will. One hundred and ninety-one articles that were official in the ninth revision of the *Pharmacopœia* have been dropped, and fifty have been added. The Latin titles of forty-five have been changed more or less. Among the more important articles that have been added are acetylsalicylic acid, arsphenamine, barbital, epinephrine, procaine hydrochloride, neoarsphenamine, quinidin sulphate, and mild and strong silver proteinates. The Committee of Revision was greatly concerned with the question whether whiskey and brandy should be admitted. After long discussion they were dropped from the ninth revision, and after an equally protracted consideration they were admitted to the tenth. Their admission was almost uniformly favored by those members of the subcommittee on scope who are in practice, and almost uniformly disapproved by the laboratory workers. There are comparatively few important changes in the strengths of official preparations which retain their former titles. Among the more important is that of the ointment of yellow mercuric oxide. It was formerly employed extensively for the destruction of pediculi, whereas it is now used mainly in ophthalmic practice. The ointment formerly contained ten per cent. of yellow mercuric oxide, but that of the forthcoming revision will contain only one per cent.

The Large Family Not Yet Extinct.—According to statistics compiled by the United States Bureau of the Census from the Birth Registration Area of the United States for 1923, the large family has not become entirely a thing of the past in this country. In that year Virginia, Pennsylvania and North Carolina each filed a certificate of a birth recorded as the twenty-sixth child of its mother, and Virginia and Maryland each filed one which was the twenty-fifth. In addition to these, in ten states certificates of a total of eighty-seven births were filed, in each instance the child being the twentieth or on up to the twenty-fourth child of its mother. Among these latter, New York filed three certificates of birth where the children were respectively the twentieth, the twenty-first and the twenty-third of the mother. Pennsylvania registered in 1923 the largest number of children born to these prolific mothers, twenty-seven women giving birth to children recorded as the twentieth up to the twenty-sixth to their credit.—*Health News,* September 28, 1925.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Health Conditions in the United States.—Surgeon General Cumming of the United States Public Health Service, says that health conditions in the United States have been generally good so far this year. Preliminary figures indicate that the death rate of the United States for the first seven months of 1925 will be lower than the average for the last five years in spite of the fact that the rate for the month of June was considerably higher than the usual rate for that month, which was probably due in some measure to the "heat waves" which prevailed over a large part of the United States.

Reports from State and city health officers indicate that most of the more common communicable diseases have been less destructive than usual this summer. For the period of eight weeks since July 1st there was a decrease from last year of twenty per cent. in the number of cases of diphtheria reported, a decrease of twenty seven per cent. in the number of cases of measles reported while scarlet fever decreased fourteen per cent.

While infantile paralysis usually increases during the spring and summer months, this year the increase has been marked in some localities. Thirty-two States reported 1463 cases of infantile paralysis for eight weeks this summer and 635 cases last year for the same period. This increase is particularly noticeable in California, Minnesota, Missouri, New Jersey, North Dakota, South Carolina, and Wisconsin. With the coming of cooler fall weather the danger from this disease diminishes.

For many years the incidence of typhoid fever has been decreasing in the United States. The general death rate in 100,000 population in the registration area dropped from 35.9 in 1900 to 6.8 in 1923. This year, however, there seems to have been a slight reaction. Since the first of July, thirty three States have reported 7173 cases of this disease, which may be compared with 5013 cases last year, an increase of forty three per cent. Some of this apparent increase, however, may be due to more nearly complete reporting of cases.

The ports of Oakland and San Pedro, Calif., and New Orleans, La., have been declared free from plague and outgoing quarantine measures have been discontinued. The Mexican authorities upon information tendered by the Public Health Service have agreed to the discontinuance of the disinfection of mails from Los Angeles, Calif., and also to the suspension of the fumigation of freight trains from that city except in cases in which the Public Health Service deems this measure necessary.

Because of the absence of yellow fever from Mexican, Central and South American ports and the very low incidence of this disease even in countries where it is present, there has been no "close quarantine" this year on account of yellow fever, which means, of course, that there has been no detention of passengers. The absence of yellow fever in Latin American countries is unquestionably due to the relentless campaigns which have been carried on against the yellow fever mosquito. The Surgeon General expressed the hope that the authorities of those countries where yellow fever infection still remains at the present time will continue the work of extermination until quarantine authorities will no longer have to consider measures against this disease.

If You Use It Once--

you will readily understand why so many physicians in choosing a reconstructive tonic invariably order or prescribe

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

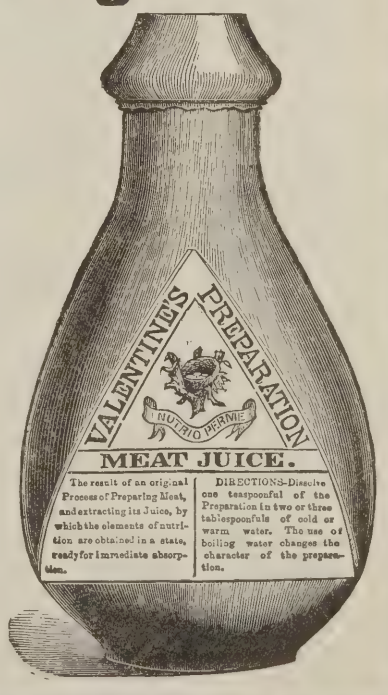
Its results will not be uncertain nor delayed, and like so many other practitioners, you will be impressed with their prompt, positive and permanent character. Best of all, your patients will be as quick to note its effects and appreciate the substantial nature of the benefits they will uniformly obtain.

The fact that Gray's Glycerine Tonic has been serving the profession for over a third of a century and that every year witnesses its increased use by discriminating medical men, "tells its own story".

The Purdue Frederick Co. **135 Christopher St., New York City**

Valentine's Meat-Juice

Whenever the **Stomach** from any cause **Rejects Food** or **Medicine, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** to **Restore** and **Strengthen.** In the **General Debility** with **Impaired Digestion** of **Phthisis,** and in the **Depressing Prostration** following **Influenza** it is recommended by many practitioners throughout the world as invaluable in their treatment.



VALENTINE'S PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Phthisis.

J. Mertens, M. D., *A. T. O. Bristol Municipal Tuberculosis Dispensaries, Bristol, England:* "I am pleased to state that the results obtained from VALENTINE'S MEAT-JUICE were very satisfactory indeed in all cases where no other kind of food could be used. It produced excellent results with wounded soldiers suffering from Tuberculosis of the lungs."

Dr. Gouel, *Physician in Chief Villepinte Hospital for Consumption, Paris, France:* "VALENTINE'S MEAT-JUICE succeeds well in cases of Anæmia and in the treatment of Tuberculosis in an advanced stage when the stomach is intolerant."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

Miscellany.

Air Mail Transportation.—In this present time of rapid transit and highest possible speed, applied to the practice and even to some of the ideals of living, means of speedy communication are vital to success in the business and professional worlds. The recent installation of air mail service is the most useful and important measure of postal improvement since the adoption of the railway postal car system in the sixties.

Perhaps few of us have realized that transmission of mail by air has been cut to less than one half the time it takes by train. Letters dispatched by air mail from New York city about nine p. m. are delivered at their address in Chicago by the first delivery the following morning, so that material to be forwarded by train from Chicago to other points is enabled to move by the first morning train instead of by one leaving in the evening. Thus delivery from Chicago to other points is expedited by at least twelve hours, and often much more. A similar gain in time is made with respect to other air mail stations where mails are transferred to railroads for distribution in adjacent territory.

It is selfevident that in many business and professional transactions this time gained is of much importance. In view of the value of such expedited mail service, the extra postage charge is negligible.

To give an illustration of one of the many ways in which physicians' work may be benefited by this shorter time for mail transportation, a research worker at the New York Academy of Medicine received a telegram from a Chicago physician asking her to abstract for him some important material which he wished to make use of in an address scheduled for the next afternoon. The telegram arrived at ten in the morning, she was able to finish making the abstracts by five that evening, and dispatched her copy to Chicago by the evening air mail. She heard later that the material arrived in time, and the doctor made use of it at his afternoon talk.

Are Calories Old Fashioned?—In his presidential address delivered before the American Neurological Association in Washington last May, Frederick Peterson (*Archives of Neurology and Psychiatry,* October, 1925) recalled the saying of Hippocrates that there are ills, no less dreadful than those of repletion, arising from deficiency of diet. Twentieth century medicine has had its attention attracted to such deficiency disorders in striking ways. It is being admonished that, "in a land literally flowing with milk and honey, several million children in the public schools suffer from malnutrition." Peterson advanced the thesis that neurasthenia, a common ailment having a professionally unpopular designation, has failed to receive the critical consideration which its widespread occurrence dictates, and that it deserves to be studied from the standpoint of nutrition and fatigue. As if to point a promising direction for the desired research, the neurologist remarks: "We are just beginning to realize that the calories have gone out and the vitamines have come in." One who has read these columns of THE JOURNAL in recent years must admit that the newly recognized food factors have found consideration and that the promise which they hold for the advancement of practical therapy has not been overlooked.

Mendel (*The Chemistry of Life,* Yale University Press, 1923) has well remarked, however, that we are living in a period of hectic anticipation of novelties, when much is expected of science; and the momentary enthusiasm for the new is apt to bring about indifference to the old. The fact is that the appreciation of the calorie idea in nutrition has not gone out but, on the contrary, has become a permanent part of every day science. Lest we forget, it may be worth while to recall what an adequate appreciation of the energy factor means for presentday medicine. Basal metabolism and its variations in disease are measured in terms of calories. The formerly unappreciated large food fuel needs of the growing child are dealt with in the same terms. As Mendel has expressed it, the better appreciation of the nutritive needs of those destined to become the rank and file of our nation when they are grown up—an appreciation based alike on experimental studies and on statistical data as to food habits—is not the least of the contributions which the science of nutrition has made to public welfare during the last decade.

The food dictators of the future will no longer be excused if they estimate the food needs of peoples in the once conventional terms of "man values" wherein the requirements of the child population were calculated as a fraction of the adult needs proportional to the smaller weight and stature of the young. The high calorie diets in fevers have revolutionized the management of the typhoid patient in determinable ways. The reduction of obesity has become an experiment in rational low calorie feeding.—*Jour. A. M. A.,* October 24, 1925.

Preventive Medicine in 1825.—That the interests of the organized medical profession in New York State in preventive medicine is by no means an entirely recent development has been pointed out by Dr. Joseph S. Lawrence, executive officer of the Medical Society of the State of New York.

In delving into the history of the organization with which he is connected, Dr. Lawrence brought to light the following interesting information which appears in the transactions of the New York State Medical Society for the year 1825.

The society held its annual meeting at Albany, twelve members being present. Dr. Felix Pascalis, of New York, was chairman of a committee previously appointed "to prepare and report prize questions." The committee's report contained the recommendations:

"That the question on the history, causes and treatment of whooping cough be continued for another year, as it appears that one only dissertation has been obtained, and it is hoped that a greater and sufficient concurrence of labor on such an important subject can yet be procured."

"That among the new prize questions to be selected be one on the American goitre, showing in what section of the State of New York, and of other states it prevails, and by what atmospheric or topographic influence that affection of the thyroid gland is aggravated, and by what remedy it can best be relieved or cured."—*Health News,* August 31, 1925.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Coffee Drinking by the Aged.—The human body with advancing age has a marked tendency to become more sensitive to stimulants such as caffeine, and the excitement of the nerve centres is less well borne in senescence than in the prime of life. With age comes increased nervous irritability and the need for more repose and sleep. The use of such stimulants as coffee and tea by old people is, therefore, of questionable propriety.

Professor Oliver T. Osborne recently pointed out (MEDICAL JOURNAL AND RECORD, December 3, 1924), some of the dangers that are likely to accompany a tea or coffee habit in old age. He says: "The action of caffeine (on the aged) is to increase general nervous irritability, cause polyuria, and especially to stimulate the thyroid and parathyroids to abnormally increased activity, with the result of more nervous irritability and muscular irritability and trembling. Caffeine often raises the blood pressure where such an increase of blood pressure is not needed." He states further that coffee and tea are likely to increase the production of uric acid and that this substance is liable to irritate the kidneys and cause muscle and joint pains in old people. Professor Osborne is of the opinion that caffeine containing beverages serve no useful purpose in the case of the aged and that caffeine should be entirely avoided except in instances where the therapeutic use of the alkaloid is indicated.

Dr. Malford W. Thewlis, in the second edition of his book entitled *Geriatrics*, calls attention to the increased susceptibility of old people to the stimulating action of tea and coffee. He urges a curtailment of the use of these drinks in senescence. The use of caffeine containing beverages with the evening meal he considers very prone to interfere with sleep. Dr. Thewlis directs notice to the supersensitiveness which old people frequently exhibit towards certain drugs; he believes that the old rule that "children and the aged cannot stand large doses" is not without foundation. Ordinary observation shows that the aged are more susceptible to caffeine than younger persons. It is not at all uncommon to hear individuals past the prime of life say they can no longer drink coffee because it keeps them awake.

Even Professor Samuel C. Prescott, who made an investigation of the effects of coffee and came to the conclusion that it is harmless for the majority of adults, says that "many individuals find with advancing years that smaller quantities of coffee will suffice," thus conceding that people do become more sensitive to caffeine as they grow older.

It is generally known that caffeine stimulates the heart's action and thus tends to raise the blood pressure. While caffeine is a vasodilator as well as a heart stimulant, its dilating action upon the hardened vessels of the aged will be less effective than in the case of younger persons; hence the increased pressure due to the heart's action will not be compensated for by relaxed arteries, and the blood pressure will accordingly increase.

Finally, it can be stated that in old age sedatives rather than stimulants, such as caffeine, are called for; old people should avoid the stimulants tea and coffee, not only because they are undesirable irritants of the nervous system, but also because they have a harmful effect on the blood pressure, cause excessive uric acid production within the body, and may, as Professor Osborne points out, produce abnormal activity of the thyroids and parathyroids.

Educational Ideals in Medicine.—Prof. John Fraser, who was appointed regius professor of clinical surgery at the University of Edinburgh in March of this year on the retirement of Sir Harold Stiles, recently delivered his inaugural lecture in the anatomy lecture theatre of the University. Principal Sir Alfred Ewing presided. Under the title of "De Novo," Prof. Fraser spoke on the course he would wish his education to follow were he given a fresh start, or, in other words, on his educational ideals. He said that he had regretfully to confess that with every year the profession of medicine became more of a science and less of an art, and that to keep abreast of the times medical teaching grew increasingly difficult. In this age of specialization the medical curriculum made such demands upon the student that there must be specialization in the preparation for it.

The previous education of the average student when he entered a university was deficient in one vital aspect—he had never been taught the logical processes upon which the acquisition of knowledge was based. The science of induction, observation, elimination of the irrelevant and inference were a closed book to him, or, if he used them, it was as a blind and purposeless instrument which bore no fruit because it was never enriched by the stimulus of purpose. From bitter experience he would say that that was a matter of the most extreme importance. Between man and man there was little material difference where the mental machinery was concerned; it was the manner by which it was worked and the method on which it was treated that spelt the difference between success and failure. He would suggest that the most productive course for the later school years would be a liberal general education, a sufficient knowledge of Latin and Greek to enable the student to understand the etymology of his profession, as perfect a knowledge as it was possible for him to acquire of French and German, and progressively intensified instruction in the basic or natural sciences—physics, chemistry, and biology. On leaving school he considered it a great advantage for a student to take an arts course before embarking on the study of medicine, because, in the words of Sir George Newman, it was "'essential to his proper professional education that it should be deeply infused and inspired by the broadest and most liberal culture, from which he may derive mental discipline, the scientific habit, and an intellectual mastery of the principles involved in his profession." Were he again a medical undergraduate, Prof. Fraser said, he would desire to be taught analytically, he would welcome the extended use of the revision and tutorial class, and he would like to see note taking at lectures abolished, its place being taken by printed synopsis slips distributed the day before. If medicine was once the fostermother of science, Prof. Fraser concluded, science was now the mother of medicine, and a medical career, preparatory, undergraduate, and postgraduate, must therefore be planned scientifically. —*Lancet*, October 24, 1925.

COLDS

tending to establish a chronic cough, are best controlled with

HISTOSAN SYRUP

Bottles of six ounces

Teaspoonful 3 or 4 times daily

Mental Hygiene.—Some of the more important activities and results of the Committee on Mental Hygiene during the past year are:

1. At the request of the Governor, helped organize Statewide Citizens' Committee on Protection of the State's Unfortunates, through which committee an intensive campaign was carried on to secure popular support for the proposed $50,000,000 bond issue for State institutions.

2. Aided the Citizens' Committee in preparing detailed recommendations as to allotment of first year's proceeds after careful study of the needs of the State institutions. These recommendations were adopted by the Governor and the Legislature.

3. Supported special bill creating a new civil State hospital, the fourteenth in the State, at Wingdale, Dutchess County, now known as the Harlem Valley State Hospital.

4. Aided in bringing to the attention of appropriating authorities the needs of the State institutions as to repairs, improvements, and fire prevention measures not provided for by the bond issue. $1,000,000 was appropriated for fire prevention and safety measures.

5. Cooperated with the State Hospital Commission, the State Commission for Mental Defectives, and the State Hospital superintendents in the further development of clinic facilities and the preventive program.

6. Continued the work of popular education in mental hygiene.

7. Kept in touch with the State Department of Education with reference to the progress of special classes for backward children. Since the State aid for special class teachers, which the committee assisted in securing, went into effect at the beginning of the last school year, 25 new classes have been established, and 15 communities, not previously having special classes, established one or more.

8. Through a special subcommittee, made a careful study of Congressional bills on immigration with reference to provisions for exclusion of the mentally unfit, conferred with authorities in Washington, and made recommendations to the Secretary of Labor. Also supported State authorities in their effort to recover approximately $17,000,000 from the Federal Government for the care of insane aliens in the New York State hospitals from 1882 to 1921.

9. Initiated special effort in cooperation with the State Hospital Commission to provide better facilities for the temporary care of patients while awaiting admission to State hospitals; made a study of psychiatric facilities at Westchester County Hospital.

10. Through special subcommittee, outlined definite program for promotion of research in mental hygiene, which program will serve as a basis for action during the coming year.

11. Issued special pamphlet and conferred with New York City authorities with reference to the provision of more adequate facilities for the temporary care and treatment of the mentally sick in New York City, and in particular the provision of a new psychiatric reception building in connection with Bellevue Hospital and Kings County Hospital.

12. Served as a bureau of advice and information relating to mental hygiene inquiries involving advice to patients as to where and how to secure treatment.

Good Faith With You!

The practicing physician has a right to expect that the remedies that seek his attention and patronage shall not be exploited to his patients. He—and he alone—is competent to treat the sick. Therefore, during the third of a century and more, that

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

has been serving the physicians of the country, it has never been advertised to the laity. In its manufacture, introduction and distribution, "*good faith with the medical profession*" has been the watchword.

Your card or letterhead will bring a regular 6-ounce bottle free of expense.

THE PURDUE FREDERICK CO.
135 Christopher St., New York

IT is easy to understand why Gray's Gycerine Tonic Comp. is today so widely used by discriminating practitioners. They know they can rely on its ethical standing no less than on its therapeutic efficiency.

Valentine's Meat-Juice

Whenever the **Stomach** from any cause **Rejects Food** or **Medicine, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** to **Restore** and **Strengthen.** In the **Depressing Prostration** following **Influenza,** and in the **General Debility** of **Phthisis, Valentine's Meat-Juice** is recommended by many practitioners throughout the world as invaluable in their treatment.

Influenza *and* Phthisis.

Dr. Boulland, *Paris, France:* "In an attack of La Grippe accompanied by complete lassitude, I used VALENTINE'S MEAT-JUICE. With this preparation I established an excellent appetite and restored my strength very rapidly."

E. H. Walker, *Resident Medical Officer Boro Isolation Hospital and Boro Tuberculosis Sanatorium, Derby, England:* "I have pleasure in stating that I have found VALENTINE'S MEAT-JUICE valuable in the treatment of soldiers discharged from the Army suffering from Pulmonary Tuberculosis."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

Miscellany.

English Women in Medicine.—The history of English women in medicine, writes Dr. Mary McKibben Harper (*Medical Woman's Journal,* September, 1925), begins with Elizabeth Blackwell, born in London, who was given the M.D. degree in the United States, returning to London to practise prior to the law for registration of doctors. Her name was included in the first register of Great Britain and Ireland. Elizabeth Garrett Anderson was the first woman to qualify in Great Britain, and she and Dr. Blackwell were the only women on the register in 1874. Sophia Jex-Blake, Mrs. Thorne and three others guaranteed a hundred pounds and were given extra mural instruction at Edinburgh University. The death of Sir James Simpson deprived them of an influential friend, and the Edinburgh episode closed with the resignation of the whole board of examiners rather than give qualifications to women. Then Miss Jex-Blake and her sympathizers founded the London School of Medicine for Women, and in 1877 the Royal Free Hospital.

Voltaire and Medicine.—At a recent meeting of the Section of the History of Medicine of the Royal Society of Medicine, the president, Dr. J. D. Rolleston, discussed Voltaire's relations to individual doctors and the medical profession as a whole, and gave some account of Voltaire's illnesses. Apart from smallpox, influenza, and pneumonia, he does not appear to have had any acute infectious diseases. He was subject to chronic dyspepsia from an early age, and suffered from catarrhal bronchitis, often associated with deafness and aphonia. He frequently complained of febrile attacks, which may have been malarial in origin. His death at the age of eighty-four was probably due to uremia following cystitis secondary to enlargement of the prostate. During his long and eventful life Voltaire was brought into contact with medical men on numerous occasions, both professionally and socially. Moreover, his works, particularly his correspondence, the *Dictionnaire Philosophique,* his tales, and to a less extent his historical works and miscellaneous essays and pamphlets, abound with references to the medical profession. In striking contrast, however, with Molière's works, in none of Voltaire's numerous plays, which for the countrymen of Shakespeare are the least readable part of his writings, does a doctor figure as one of the *dramatis personæ,* nor are there more than one or two vague references to medical matters.

Among the numerous doctors whom Voltaire consulted the best known were Silva, physician to Louis XIV, Boerhaave, whose name occurs often in Voltaire's works, especially in connection with chemistry, and Tronchin, whom he described as the greatest physician in Europe, and the only one who understood nature. Voltaire was far from being an ideal patient. Like Herbert Spencer a hundred years later, he was too fond of arguing with his doctors and too little inclined to carry out their instructions. He told one of his medical correspondents that he had read more works on medicine than Don Quixote had on chivalry.

Throughout his writings many references are to be found to some of the masters of medicine, such as Hippocrates, Rhazes, Servetus, Harvey, and Sydenham, as well as to celebrated anatomists such as Vesalius, Ruysch, Bartholin, and Vieussens; but the medical work with which he was probably most familiar was that of Astruc on the venereal disease. The passages in which Voltaire indulges his satirical humor at the expense of the medical profession are few in comparison with those in which he expresses his admiration and gratitude, and, apart from the stories, are chiefly to be found in his correspondence, where (Dr. Rolleston remarked) they are not to be taken too seriously. On the other hand, Voltaire was scathing in his denunciation of quacks, of whom the most notorious was the Swiss uromantist Schuppach, and vented his ridicule on many superstitious and erroneous doctrines connected with normal and morbid processes.

Dr. Rolleston's paper was accompanied by an exhibition of Voltariana, mainly arranged by the well known antiquary, Mr. A. Forbes Sieveking. These objects included an unpublished portrait by Woolidge, the first English edition of the *Lettres sur les Anglais,* which contains a celebrated letter on inoculation, of which Voltaire was an ardent propagandist throughout his life, and the original manuscript of an English letter by Voltaire, lent by Mrs. Francis Edwards. —*British Medical Journal,* October 31, 1925.

The Future of the Medical Sciences.—A Budapest scientific periodical, according to the *Medical Press and Circular,* has sent questionnaires to scientists asking for their opinions as to the future of the various branches of science. Perhaps the most interesting of the answers was that of Dr. Hümér Hültl, of the department of surgery at Budapest, who said that, taking as a basis the work of recent years, we are entitled to prophesy the following future for teratology and nosology, the former dealing with hereditary anomalies and the predisposition to disease, by protecting maternity, and by means of hygiene and eugenics. "In several states of America and also in Switzerland the sterilization of the unfit is lawful. The bill in regard to castration of those who from the community cannot expect anything, is before the special Commission of the German Reichstag. It can be hoped that those deforming and heroic operations now performed on cancer patients, by which the lives of hundreds are saved, will become superfluous in the next score of years. An American physician, Miss Maud Slye, succeeded in cultivating stocks of mice, in which all the individuals developed cancer, but could not be inoculated with it at all. It seems probable, therefore, that the tumor is only a symptom of the cancerous organism. In the next twenty-five years serology will find out why the organism is able to resist cancer, and then the utter anarchy of the cancerous cells will come to an end. On the other hand, if such a disease befalls the organism, necessitating an operation, the danger will be reduced to a minimum. It can be expected that future progress will greatly decrease the risks of narcosis. Surgery is losing ground, but we can anticipate that it will gain new domains. Theoretically it is not at all impossible that the surgeon will transplant healthy organs to replace unsound ones, just as the watchmaker substitutes a new wheel for an old one."

THE VALUABLE MEDICINAL PROPERTIES

of Dr. Siegert's

ANGOSTURA BITTERS

(Elix. Ang. Amari Sgt.)

are established by the testimony of medical practice throughout the world for three generations. It has wide scope as a flavoring agent in prescriptions, and also as a tonic and direct stimulant of appetite and metabolism. For a complimentary sample and particulars write to

"Diabetes, Diabesan and a Grateful Patient"

Point Pleasant Beach, N. J.,
September 29, 1925.

Dr. Werner.
My dear Friend:—

I can call you friend as "Amicus certus in re incerta cernitur."

When I left the hospital last May after the "Allen Starvation Treatment" I weighed only 106 lbs., very weak and debilitated with glycosuria and glycemia, very much discouraged and melancholy. Dr. Shoub wrote me that he had seen very good results from the "Rational Treatment of Diabetes," by Dr. Werner, President of the Solosan Company of Morristown, N. J. With much misgiving I began your treatment about July last.

I want to congratulate you on my condition. I now weigh 122 lbs., very good color in my face, no sugar in the urine, very little blood sugar, no diacetic acid, no acetone.

I feel much stronger and do not tire easily, as before. I sleep better and not so nervous. I feel better and clinically proven to be better.

A grateful patient,
Rev. Joseph V. Sweeney.

Tattooing Among Primitive Peoples.—Dr. Bertholin, of Tunis, has recently published an interesting memoir on the neolithic origin of tattooing among the true aborigines of Northern Africa. The practice of tattooing among them is "a prolonged archaism," of which we must look for the first indications in quaternary times. The figures given by him show that more than three thousand years ago the tattooing on figurines found in the tombs of Nagada is found today in the same characters, with the drawings identical, on the same parts of the body, among the Berbers of Northern Africa.

Among these primitive peoples the ornamental drawings varied but little. The same types of lines and figures was used on pottery, in drawings on stone, and for the paintings and tattooings made on human bodies. Such are the concentric curves, crossbars, triangles and notched lines. These tattooings of primitive men are marks of relationship, signs of recognition, immutable amulets attached to the individual, symbols which were reproduced on the stylus of his tomb.

In proportion as the social milieu was developed, these costumings were adapted to the new mode of life. But throughout history tattooing remains a religious rite, a hieratic symbol, a consecration. It is sometimes a record of family or caste, sometimes a professional emblem, sometimes a talisman, sometimes a brand of disgrace. It was among the Thracians, according to Herodotus, a sign of aristocracy which the lower classes were not entitled to wear. Antique vases of the fifth century show maenads or Thracian women tattooed on the arm or leg with the picture of a fawn; the fawn was the symbol of Dionysius; in the bacchic orgies the maenads dismembered it alive and devoured it raw. On the contrary, classic Greece, the period of Homer, with its admiration for physical beauty, did not adopt the practice of tattooing.—Translated from *Æsculape*.

Nicolas Monardes and His Drug Catalogue.—An interesting recent reprint by Constable of London is Joyful Newes Out of the Newe Founde Worlde, written in Spanish by Nicolas Monardes, physician of Seville, and Englished by John Frampton, Merchant, Anno 1577; with an introduction by Stephen Gaselee. In commenting on this reprint, the *Medical Press,* London, tells us that Monardes was born in Seville in 1493, and, after pursuing medical studies at the university, returned to practice in his native city. Spain was approaching her zenith. The wealth of the Indies was pouring in, and, apart from material riches, new medicines unknown to European physicians, but reputed by the natives to possess a potency almost magical, were introduced into the science of medicine. It was the story of their curative virtues, of the wonderful results which they had wrought when administered to the Indians, the conquistadores, and the European colonists, that induced Monardes to compile several catalogues of the drugs of the Indies. The above mentioned reprint is one of these. Monardes devotes considerable space to a description of tobacco, and Frampton adds a supplementary section of his own entitled "Nicotaine," after Nicot, the French ambassador at Lisbon, who was instrumental in introducing the weed to his own country by sending an account of its virtues and delights to Catherine de Medici, then Queen.

Monardes describes how the smoking habit spread from the natives to the Spaniards, and the deep narcotism effected by it, those indulging lying as though dead for hours, and experiencing illusions and visions which he attributes to the devil. He deals more fully, however, with the external application of tobacco as a plaster, attributing to it the power of purifying and healing wounds, and with the native habit of chewing it to allay the pangs of thirst and hunger.

Gifts to Jefferson Medical College.—Announcement has been made of the presentation by Dr. J. Ackerman Coles, of Newark, N. J., of two valuable gifts to Jefferson Medical College. One is a portrait of William Harvey, by Van Dyck, which formerly belonged to Oliver Wendell Holmes. Dr. Coles had already given to the library of the college a copy of Geneva edition of the works of Hippocrates, printed in 1657, and translated into Latin by Foesius. This was long considered the best of the translations for purity, fidelity to the text, and excellence of annotations. It contains the glossaries of Erotian, Herodotus (the physician), and Galen, and in addition the *Œconomia Hippocratis,* a collection of all the obscure terms to be found in the works of Hippocrates.

Goitre in Paintings by the Old Masters.—In the August issue of *Nederlandsch Tijdschrift v. Geneeskunde,* Van Leersum gives ten reproductions of Madonnas by old masters, and a list of other portraits in which the artist has depicted more or less thyroidal enlargement. He also notes the prominence of the thyroid cartilage in female portraiture and sculpture of the same period, and deduces from the large number of instances in which each of these enlargements are represented that in the fifteenth and sixteenth centuries, to which these portraits refer, such pathological conditions were common. This being so, he argues that the modern prevalence of goitre is not to be attributed to causes which have arisen during recent times.—*Medical Press and Circular,* October 28, 1925.

The Correlation of Federal Health Agencies.—Linsly R. Williams, New York (*Journal A. M. A.,* November 7, 1925), calls attention to the present lack of correlation of federal health agencies, many of which are accomplishing very valuable and significant results. While making certain general suggestions for coordination, no recommendation for any definite plan is made. There is no doubt that in the interests of efficiency there must be practical coordination and that this should be brought about as soon as possible. While the care of the public health in this country is, under our form of government, primarily vested in the individual states, the federal government does have certain proper duties, such as those involving foreign and domestic quarantine, interstate commerce, research, revenue matters, and the care of the health of the wards of the government. These duties can undoubtedly be more effective and can contribute more completely to the enhancement of national health and happiness, if they are conducted in a more unified way, thus supplementing the many notable achievements which these federal bureaus already have to their credit.

Here are 9 Forms of Mercury

In Ampoules for the Treatment of Syphilis

A FORM TO SUIT INDIVIDUAL PREFERENCE. For nearly five centuries, mercury has stood pre-eminent as an antileutic agent. It seems to matter little in what form the mercury is used, so long as it is given in therapeutic doses. The form of administration becomes a personal preference, and the ampoules offered by Swan-Myers Company afford a variety of forms sufficient to suit the ideas of most physicians. Select the Mercury ampoule which you prefer and order a package from your dealer. If he cannot supply you, order direct.

COUNCIL PASSED

CAPROKOL

(HEXYLRESORCINOL S & D.)

$C_6H_3(OH)_2C_6H_{13}$

Indicated in the treatment of infections of the urinary tract.
Approximately 45 times the germicidal power of Phenol.
Non-toxic in therapeutic doses.
Renders the urine a germicidal solution.

FOR ADULTS:—Soluble Elastic Capsules CAPROKOL, (Hexylresorcinol S & D.). Supplied in prescription boxes of 100. Each capsule contains 0.15 gram CAPROKOL, (Hexylresorcinol S & D.) in a 25% solution in Olive Oil.

FOR CHILDREN:—Solution CAPROKOL, (Hexylresorcinol S & D.). Supplied in four-ounce prescription bottles. Each teaspoonful contains 0.1 gram CAPROKOL, (Hexylresorcinol S & D.) in a 2 1-2% solution in Olive Oil.

Report by the Children's Bureau on Juvenile Courts.—Better facilities for scientific treatment of the child delinquent and larger, better trained, better paid probation staffs, are the outstanding needs of the juvenile court in the average city, according to a report recently made public by the Children's Bureau of the United States Department of Labor.

The report is based on data furnished by the children's courts of ten representative cities—Boston, Buffalo, Denver, the District of Columbia, Los Angeles, Minneapolis, New Orleans, San Francisco, Seattle and St. Louis. Conferences on juvenile court standards have resulted already from the Bureau's inquiry, and a committee of judges, probation officers and others directly concerned has formulated standards for the better organization and administration of the juvenile court.

Summarizing the detailed consideration of the methods and organization of the ten courts studied, the authors of the report state: "In general the resources at the disposal of the court seemed to have been developed in a haphazard manner, and did not fit together to form a complete community program for the care of delinquent and dependent children. The court therefore was limited in the treatment it could prescribe." Important points considered by the Bureau were the amount of time devoted by the judge to juvenile court work, the training and size of the staff, the method of dealing with children being detained pending hearing, the facilities for physical, mental and social examination of the child, the character of the hearings, the cooperation between the courts and the social forces of the community. With regard to these points the report states:

Only five of the ten courts were served by judges devoting full time to juvenile court work—those of Boston, Buffalo, Denver, New Orleans and the District of Columbia, though in Los Angeles the judge gave part of his time and a woman referee full time. The number of probation officers attached to the courts varied from four to twenty-six. In seven of the courts the majority of the probation officers had had no previous experience in occupations allied with probation. Of conditions of employment among the probation staffs, the report states that the low salaries paid in most of the courts studied and the absence of defined requirements for entrance into the probation service naturally resulted in probation staffs whose members, as a rule, had little preparation for their work through education or previous experience. Study of the child and his family and successful reconstructive work not only call for certain indispensable personal qualities, but also demand the knowledge and skill that come only from training and experience. "To secure such service, it is essential that the authorities to whom probation officers are responsible and the general public recognize its character and importance and provide compensation adequate to attract and hold a qualified personnel. In spite of these limitations, however, the Children's Bureau states that what facts could be secured indicated that the probation method was to a large extent successful.

Policies toward the child who is held pending a hearing varied. One of the well established principles in juvenile court work is that children should not be detained in jails or police stations. Yet eight of the cities reported such detention of children, in some cases as a rare occurrence, in others as a comparatively common practice. Special detention homes for children waiting court action are usually considered the most feasible arrangement for large cities, and six of the ten cities studied had such buildings available. Some of the detention homes, however, were seriously overcrowded, and more space for recreation and better supervision of the children was needed. Another plan of detention which does not involve the use of a special building had been tried out in Boston, and is believed by the Bureau to be especially applicable to courts is small cities or rural districts. This is the plan of placing the children for detention in private families to which a monthly subsidy is paid in addition to a certain sum for each child.

Facilities for social investigation and thorough study of the child's physical and mental condition were limited in the courts. Only the Boston court had provision at the time of the inquiry for well rounded study of all important cases, including the social, physical and mental factors. The work of the Judge Baker Foundation of Boston is discussed by the report. Child guidance clinics serving the juvenile court and other agencies have recently been established in St. Louis, Minneapolis and Los Angeles. One of the important features in a number of the courts was the effort made to adjust cases informally. In the Denver court 72 per cent. and in the Seattle court 76 per cent. of all boys' cases were settled is this way. In connection with the formal court hearings two points were considered important—whether hearings were held at frequent intervals so that children were not detained for more than short periods; and whether the public was excluded from the hearings. It was found that in some of the courts delinquency cases might be heard at any time, in others there were five regular hearings a week on such cases, while in still others there was only one such hearing a week. Under the last arrangement, a child might be held as long as nine or ten days.

In connection with its study the Bureau asked the judges and chief probation officers of each court to state in what respects they considered the resources at the command of their court adequate. The statements of these officials emphasized the need for more probation officers, for more adequate provision for delinquent children who do not require commitment to state institutions, better institutional care for the children who do need it, more adequate provisions for the care of mental defectives, and for placing dependent and neglected children in family homes. In conclusion the report stresses the importance of the cooperation of juvenile courts with school departments and social service agencies and institutions. It points out the opportunity of the school in the prevention of delinquency and the conditions that would make it possible for the educational systems developing special methods of dealing with conduct to function more effectively in this respect. In several of the cities studied the school departments were problems, including visiting teachers, psychological clinics, and attendance officers having special equipment for their work and special day schools or classes for truants, unmanageable or incorrigible children.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

G. W. CARNRICK CO.

417-421 Canal Street - - - NEW YORK, N. Y.

A Successful Garden Community Under Way.—In 1924 a group of public spirited New Yorkers, realizing the necessity of making available to the average citizen of New York and its vicinity sanitary, light, airy homes, and that the question was one only of ways and means, got together and formed the City Housing Corporation. Its capital was put at $2,000,000, and its management placed in the hands of experienced administrators and real estate investors. All corporation officers were to serve without pay.

The corporation stated its aims as follows: 1. To develop better plans and methods for home and community building, and to demonstrate the advantages of large scale purchasing of land and quantity production of homes. 2. In doing this to build the type of low priced houses that are needed by self respecting citizens of New York. 3. To show home seekers of small income that they can own first class homes for what they are now paying in rent for less satisfactory places. 4. To encourage and develop cooperative methods of home ownership. 5. To demonstrate the value of outdoor play space adjacent to homes and to convince builders and operators that this can be supplied on a practical business basis. 6. To arouse the public to a recognition of the social obligation resting upon it to make it possible for citizens of moderate means to live in decent houses.

The first project of the corporation was the purchase of a tract of land at Sunnyside, Long Island, in March; by January, 1925, 128 families were living in one and two family houses and apartments. All the buildings are of brick, attractively designed and constructed, and equipped with all the modern conveniences. Since the houses are only two rooms deep, every room is an outside one. The corporation is already building its second unit, which will house 125 families, and will occupy the same percentage of landscapes, which amounts to about thirty per cent., against the seventy per cent. permitted by the New York State law. This means that seventy per cent. of the land is to be devoted to lawns, wading pools, basket ball and tennis courts, sand piles, swings, etc. Eventually twelve hundred families will have homes on the corporation's property. Stores are only a block away, and the public school and churches within walking distance.

All the community houses are bought and sold, none rented, so that the capital is kept liquid, and continually turned over in home building experiments and demonstrations. Sales are made on easy monthly payments. The cost of the houses ranges from $8,500 for a six room one family dwelling, to between $11,500 and $13,500 for two family dwellings of from eight to eleven rooms. The average income of purchasers has been $2,400. The occupations represented are building mechanics, office employees, teachers, chauffeurs, salesmen, housekeepers, grocers, printers and cooks.

The corporation's chief aim is to provide as many homes as possible for people of moderate incomes, and to demonstrate at the same time the business soundness and practical character of such large scale building to commercial builders, thus giving to those of moderate means the same advantages of desirable surroundings now available only to the wealthy.

Good Faith With You!

The practicing physician has a right to expect that the remedies that seek his attention and patronage shall not be exploited to his patients. He—and he alone—is competent to treat the sick. Therefore, during the third of a century and more, that

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

has been serving the physicians of the country, it has never been advertised to the laity. In its manufacture, introduction and distribution, "*good faith with the medical profession*" has been the watchword.

Your card or letterhead will bring a regular 6-ounce bottle free of expense.

THE PURDUE FREDERICK CO.
135 Christopher St., New York

IT is easy to understand why Gray's Glycerine Tonic Comp. is today so widely used by discriminating practitioners. They know they can rely on its ethical standing no less than on its therapeutic efficiency.

Valentine's Meat-Juice

Whenever the **Stomach** from any cause **Rejects Food** or **Medicine, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** to **Restore** and **Strengthen.** In low forms of **Pneumonia** and **Exhaustion,** in the **General Debility** and **Depressing Prostration** following **Influenza** it is recommended by many practitioners throughout the world as invaluable in their treatment.

Pneumonia *and* Influenza.

William H. Peters, M. D., *Admitting Physician, Camp for Consumptives, State of Rhode Island, Providence, R. I.;* "VALENTINE'S MEAT-JUICE was the only nourishment retained by my five-year old daughter during an attack of Pneumonia. I consider that it saved her life and believe it to be the best product of its kind."

Cavalier Dr. Enrico Ballerini, *Late Surgeon to the Hospital of Rome, Italy:* "I have used VALENTINE'S MEAT-JUICE in the treatment of patients, and also personally, after having been very ill with Influenza, and I must say it is an excellent tonic in conditions of great organic weakness. It is also very agreeable. I have prescribed it with the greatest satisfaction for convalescents and invalids restricted to a liquid diet."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S
PREPARATION
NUTRIO PERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Voltaire and English Doctors.*—Although we have no record of Voltaire's having been attended for his various illnesses by any physician of London during his residence there, he appears to have had the acquaintance of a number of the medical men of his time. The first of these was Sir Hans Sloane, elected president of the Royal College of Physicians in 1719, and who succeeded Sir Isaac Newton as president of the Royal Society in 1727, the year following Voltaire's arrival in England. The great Frenchman gave Sloane a copy of his English Essays, and of his Essay upon Epic Poetry of the European Nations, both books being autographed.

The next member of the medical profession whom he met in London seems to have been William Cheselden, to whom he alludes in several passages of his works as a personal acquaintance. He describes the famous surgeon's successful operation in a case of cataract, quotes him as having said that he was the first to have his instruments made in London, and refers to several of his opinions on medical and surgical subjects.

Richard Meade is also mentioned a number of times by Voltaire, although in none of these passages does he claim him as an actual acquaintance. He quotes Meade as having said, in discussing the question of the poisonous nature of powdered diamonds, "If I were offered two big diamonds on condition that I swallowed one in powder, I would accept the bargain." Also, Meade's name appears on the list of subscribers to the London edition of *La Henriade,* which contains also the names of three other physicians, given as Dr. Brocksom, Dr. Misobin, and Dr. Chamberlain. The second was probably John Misaubin, who has been credited with being one of the four physicians mentioned in *Tom Jones,* and also as having served as the model for the doctor in the third scene of Hogarth's *Marriage à la Mode.* The other two were probably Dr. Noel Brocksom and Dr. Hugh Chamberlain, the last of the celebrated family of obstetricians.

Among less well known physicians with whom Voltaire was acquainted in London were Dr. Richard Towne, author of a book on diseases of the West Indies and translator of parts of *La Henriade;* John Arbuthnot, James Keill, and Henry Pemberton. That Voltaire had some knowledge of the English medical classics is shown by his allusions to Harvey, Sydenham and Freind. He probably also studied the Philosophical Transactions and gained from them his knowledge of inoculation, of which he was an enthusiastic supporter throughout his life. Other English medical men mentioned by him are John Locke, whom he vastly admired, Samuel Garth, author of *The Dispensary,* Saint-André, court anatomist to George I and the dupe of Mrs. Tofts, the rabbit breeder of Goldaming, and the anonymous author of *Onania,* of which Voltaire tells us that about eighty editions were published, although he also suggests that this was merely a bookseller's trick to gain readers.

Among Englishmen who visited the great philosopher at Ferney were at least three physicians. The most famous of these was Oliver Goldsmith who in his Memoirs of Voltaire has given us a description of the conversation in which Voltaire defended the English against Diderot and Fontenelle. The two others were Samuel Sharp, surgeon to Guy's Hospital, and John Moore, who in one of his books gives us a remarkable description of Voltaire as an old man.

*Abstract of the address made before the Fifth International Congress of the History of Medicine at Geneva, July, 1925, by Dr. John Davy Rolleston.

Pepys and Science.—The Master of Christ's College, Cambridge, himself a writer of picturesque accuracy, is the very man to write with understanding and sympathy about that delightful seventeenth century Horace Walpole whom we know as Samuel Pepys, secretary to the Admiralty, says an editorial writer in the *Lancet,* October 24, 1925. In the current *Quarterly Review,* he goes on to say, Sir Arthur Shipley points out how science in Pepys's time was the "object of an insatiable curiosity, perhaps in a way childish," and how Pepys himself was insatiably curious. Nothing was too odd or too trivial for his notice and record. On March 14, 1662, he met a German, Dr. Kuffler, who came "to discourse with us about his engine to blow up ships," a subject naturally interesting to a high official of the Admiralty. Although he only began to learn the first four rules of arithmetic in his thirtieth year, he was yet a great friend of Edward Cocker, who engraved a slide rule for him.

On account of his defective vision Pepys took much interest in optics and records how in company with Mr. Spong and "my twelve foot glass"—i. e., one with a focal length of twelve feet—"we did see Jupiter" and had "several fine discourses upon the globes this afternoon, particularly why the fixed stars do not rise and set at the same hour all the year long, which he could not demonstrate, nor I either." Let us hope that comprehension is wider nowadays. Pepys was elected to the Royal Society in 1665 and in 1684 became its President. It was during his term of office that Newton's immortal work, the *Principia,* was accepted and published by the Society under Pepys's imprimatur. Many passages in the diary are quoted by Sir Arthur Shipley, which show how constantly Pepys attended meetings and demonstrations, several of which dealt with transfusion of blood. He also at "my Lord Crewe's" and other places met various learned persons who told him extraordinary stories about swallows hibernating, a belief which even Gilbert White held, and one of these, Mr. Templer—"an ingenious man and a person of honour he seems to be," says Pepys with unwonted caution—told a story of how serpents in Lancashire catch larks by crawling under a soaring lark and with wide open mouth eject their poison, whereupon the lark falls down into their jaws. Many similar startling episodes in natural history will be found in the pages of the Rev. Edward Topsell, who wrote a *History of Beasts and Serpents,* to which Dr. Muffett contributed a section upon insects. Pepys relates a story from Muffett about Dr. Caius, and it is not unreasonable to suppose that he was acquainted with Topsell's book, the matter of which would certainly have interested him. So many facets did Pepys present to the world that, as Sir Arthur Shipley puts it, "he appears to have been almost globular."

In recommending an infant food —consider its nutritive value first

Injuries to the Head and Their Sequelæ.—Dr. Raphael Lewy, chief medical advisor of the Bureau of Workmen's Compensation, in an interesting article on head injuries (*Bulletin* of the Medical Division of the New York State Department of Labor) says that since the thickness and resistance of the skull varies in different individuals, injuries to the skull may have very different sequelæ. In thin skulls, a comparatively slight injury may be the cause of death. Since the vault is stronger than the base, fracture of the base of the skull is frequent. Fracture of the skull is not necessarily caused by very severe trauma, nor need the external manifestations of the injury correspond to the severity of the posttraumatic intracranial sequelæ. Hence a skull injury may be followed immediately by severe intracranial symptoms; a fracture may also occur without immediate or serious intracranial sequelæ. "In all head injuries," writes Dr. Lewy, "it is most important to determine whether the posttraumatic sequelæ are due to involvement of the meninges or to the brain substance, and it is therefore a *conditio sine qua non* that the clinician should be familiar with the topography of the important brain centres."

Falls or objects falling on the head may result in contusions of the soft tissues, blood effusions between the scalp and periosteum, wounds of the scalp with or without infection, hematoma beneath the periosteum, fractures of the external or internal table, and fractures of the entire thickness of the skull with or without intracranial injuries. Contusions of the scalp, diagnosed by local swelling, heal in a short time after the absorption of the blood. They may be accompanied, however, by concussion of the brain, depending upon the weight or height of the falling object. If the trauma causes a hemorrhage beneath the periosteum, subperiosteal hematoma may result. If no external wound exists, the blood effusion heals by absorption without any special treatment, usually application of an icebag being sufficient. Any of the conditions enumerated may be accompanied by concussion with manifestations immediate or developing soon after injury. Often headache and vertigo persist long after all other evidence of injury has disappeared. Contusions accompanied by external wounds may result in serious infection, which often heal with painful adherent scars, the causes of future headache and neuralgia. In serious cases, erysipelas may be a complication, causing painful edema of the tissues of scalp and forehead, and often extending over the whole surface of the skull and involving the meninges. This latter complication frequently results in death.

Concussion of the brain is often a sequel of trauma. It may follow contusions of the soft tissues with or without fracture, but most frequently follows fractures. Its most important indication is loss of consciousness, which may be of short duration, or, if accompanied by intracranial hemorrhage, may last until the pressure is relieved. The unconsciousness may be accompanied also by Cheyne-Stokes respiration and by disturbances of the cardiac apparatus, due to irritation of the medulla. The pupils may be irregular and unresponsive to light. If unconsciousness persists, the pulse becomes rapid, small and often hardly palpable, and there may be loss of sphincter control. Those who have suffered from concussion and recovered from immediate symptoms are often able to resume their work for a certain length of time. Then suddenly headache and vertigo may develop, usually subjective and not to be confirmed by any physical examination. There is some controversy among physicians as to these symptoms, some insisting that the patient is a malingerer, and others that the headache and vertigo are attributable to the original skull injury. Dr. Lewy states that his long experience with such cases has led him to the conclusion that, whenever an injury to the skull with or without a fracture has been accompanied by unconsciousness, although of short duration, there is a disturbance in the relationship of intracranial structure, which may manifest itself as headache and vertigo without accompanying physical signs long after the injury.

Acquaintance with individual history plays a large and important part in diagnosing and treating injuries of the skull. Hereditary neurotic tendencies must be taken into account in differential diagnosis between posttraumatic functional neurosis and wilful simulation. Dr. Lewy states that he has found simulation *in toto* exceptional, but exaggeration of existing symptoms frequent. Infection with syphilis and addiction to alcohol may precipitate, after head injury, functional or organic nerve conditions, although the injury may not have shown any serious external manifestations. Compression of the brain is a condition often following fracture of the vault of the skull. The cause of this may be a depressed bone fragment, increased intracranial pressure from hemorrhage, or most frequently laceration of the middle meningeal artery. The clinical picture differs from that of concussion in the flushed face, small, contracted pupils, slow pulse, restlessness, and paralysis of the part of the body corresponding to the involvement of some focal nerve centre due to the compression. If the patient survives, he may suffer from the same sequelæ as those of concussion, and in addition from those resulting from cortical irritation and thickening of the meninges, later developing into pachymeningitis and accountable for the epileptiform and paralytic conditions often following such injuries. In lesions involving the cerebellum, the most important subjective symptoms and clinical signs are headache and vertigo, unsteady gait, a feeling of falling to one side, inclination to nausea and vomiting, pain in the occipital region, and a peculiar spasm of the muscles of the back of the neck. Sometimes posttraumatic diabetes and epileptiform seizures follow.

Since fractures of the vault of the skull often exist without external evidence, they are frequently overlooked, especially in cases of fissure fractures without displacement. Therefore all injuries to the skull should be subjected to a thorough stereoscopic radiographic examination. Cases of fissure fracture without displacement may exist for months without any posttraumatic disability, and then a neurosis may develop. Such cases should be followed up for at least a year. Fractures of the base of the skull, also, need not show physical signs nor be accompanied by unconsciousness. In such cases, weeks after the injury, headache, vertigo, loss of equilibrium, and defective

hearing may develop. Fortunately, however, most fractures of the base of the skull show distinct clinical signs. If the fracture involves the anterior fossa, we have ecchymosis of the lower eyelid, bleeding from the nose or nasopharynx, and sometimes escape of the cerebrospinal fluid from the ear or nose, with or without unconsciousness. If the fracture is in the middle fossa, there is bleeding from the ear, with later buzzing and deafness, and, if the vestibular apparatus is involved, unsteady gait. Care must be taken not to overlook traumatic meningitis, for, if the clinical signs enumerated are accompanied by rise of temperature and pulse rate, and continuous fever, headache and interference with vision, meningitis must be absolutely considered. If, in addition, ptosis of the eyelid is present, or strabismus or nonreaction of the pupil to light, and mental cloudiness, with or without unconsciousness, meningitis is certain. If infection of the auditory canal already exists, such fractures can predispose to the formation of purulent meningitis, sinus thrombosis, or abscess of the brain.

Acute suppurative mastoiditis, either with or without septic meningitis, has been known to develop, following injury to the base of the skull, in persons who prior to injury suffered from a chronic otitis media. Pachymeningitis, a hyperplasia of tissue causing thickening of the dura mater and thus creating mechanical pressure, may permit the sufferer to return to work, but he will certainly complain of a single, constant symptom—a localized, dull, pressing headache. There is no other physical manifestation; yet, sometimes after months or years, epileptic seizures may occur, or a psychosis, or a complex resembling dementia precox or manic depressive insanity. It is matter of constant controversy in the medical profession whether such states can be a sequel of head injury, especially when there was no fracture, concussion, nor immediate disability.

The writer has come to the conclusion that "In such persons where a careful study of the past personal history presented evidence of an endocrine imbalance or emotional instability, the character of the injury and the subjective symptoms in the interval between the injury and the resultant psychosis, all point to the fact that the trauma to the skull must be looked upon as a precipitating or contributing factor in the development of the psychosis." Injuries to the skull, especially fractures with or without infection at the site of the injury, may be a primary or activating cause of brain abscesses, especially in the cortex. Abscesses may manifest themselves at once, or become incapsulated and not be evident for years.

Tumors of the brain may also be activated from injuries, but the trauma *per se* is never the primary cause. It produces only a *locus resistentiæ minoris* where dormant embryonic cells already exist. Such injuries may also be a contributing factor to the development of gumma of the brain in persons infected with syphilis. As to the place of brain injuries in affecting paresis, the writer believes that they are a contributing factor in precipitating a constitutional infection in a brain where resistance has been lowered by some trauma.

OF
MEDICINE AND SURGERY

With a Symposium on Endocrinology

DECEMBER SIXTEENTH
1925

PUBLISHED BY THE A. R. ELLIOTT PUBLISHING COMPANY
53 Park Place, at West Broadway - New York, N. Y.

After all the most important thing is to relieve the distressing symptoms of digestive disorders first and then apply the systematic remedies for proper correction of functional defects. Do you know that thousands of doctors recommend six (6) Bell-ans dissolved in a glass of hot water for immediate relief in digestive disorders?

Bell-ans gives results; that is why it is now universally used.

Lilly's Scarlet Fever Antitoxin

The United States Public Health Service issued to Eli Lilly and Company the first license to manufacture Scarlet Fever Streptococcus Antitoxin.

Lilly's Antitoxin is made by the Dochez method, which makes it possible to obtain an antitoxin many times stronger than the official requirements. Its great potency permits a dose of very small volume.

Each lot of Lilly's Antitoxin is tested by a control lot which has been proved therapeutically.

Lilly's Antitoxin is offered only in the concentrated form: A-80, Prophylactic Package; A-82, Therapeutic Package. Write for further information.

A ONE-DRUG Cough Remedy

IN contrast with the "shot gun" cough remedies, **THIOCOL SYRUP "ROCHE"** contains *only one drug*, thiocol.

No narcotic, not a single cough deterrent, not another active cough combatant is in it—THIOCOL *alone* is sufficient. A pronounced and effective sedative expectorant which exerts a beneficial effect on the respiratory tract, and definitely aids in subduing the cough.

"Thiocol..... is comparatively tasteless, does not disturb digestion, and is non-toxic." (*New and Nonofficial Remedies of the A.M.A., 1925, p. 101.*)

These advantages, and the absence of any cloying sweetness, stamp **THIOCOL SYRUP "ROCHE"** as a distinctive remedy—and one which can be given with safety to the youngest children.

Calcium and Phosphorus

The profound physiologic importance of calcium and phosphorus, especially in the so-called wasting diseases, is becoming increasingly evident, and the best form of calcium and phosphorus for administration is unquestionably calcium glycerophosphate.

ESKAY'S
NEURO PHOSPHATES

contains calcium and phosphorus in the form of glycerophosphate, is rapidly absorbed and does not cause gastrointestinal irritation on long-continued use, as do the usual calcium salts.

SMITH, KLINE & FRENCH CO.

See the "Point"?

68172 © 1925 H.K.M.Co.

That point is the distinctive feature of this improved vaccine container. A most important feature it is, too, because it simplifies the technique of vaccinating against smallpox.

This "business end" on the vaccine tube enables me to vaccinate rapidly and that is a big help when I have a large group to vaccinate.

"Tube-Point" is the name given to this combined scarifier and vaccine container—the only vaccine "point" licensed by the U. S. Government.

It is made entirely of glass, in one piece, with the vaccine virus hermetically sealed in the tube.

The scarifying point, being of glass, avoids all semblance or suggestion of a surgical operation, thus also avoiding alarm and fear on the part of the patient.

This tube-point is an exclusive Mulford feature, having been originated in the Mulford Laboratories, which have pioneered in Smallpox Vaccine production for more than a quarter century.

H. K. Mulford Co., MJAR
Mulford Bldg.,
Philadelphia, Pa.

Please send me free sample of Mulford Smallpox Vaccine Tube-Points.

Name .....

Address .....

.....

The activity and purity of Mulford Smallpox Vaccine Virus is assured by extreme care in preparation, proper aging and rigid testing at every step in the process.

The combination is ideal—a thoroughly reliable vaccine virus in a ready-to-use container. If you have not seen it, ask H. K. Mulford Company, Philadelphia, for a sample. Use the coupon.

NOTE.—Mulford Smallpox Vaccine is also available in plain capillary tubes, for the benefit of physicians who prefer to vaccinate by the puncture method, or otherwise.

BRONCHIAL AFFECTIONS

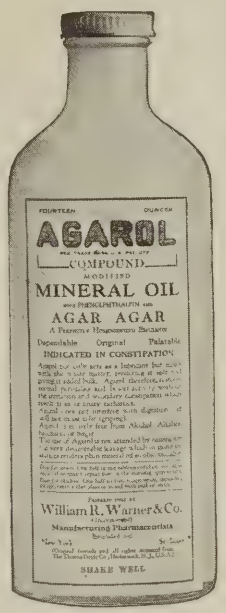
THE ELIMINATION OF UNCERTAINTY



AGAROL is the *original* Mineral Oil—Agar-Agar Emulsion, and has these special advantages:

Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances; not habit forming.

AMONG the newer remedies of proven worth, there is hardly one that has won the favor of conservative medical men to so certain or complete a degree as

AGAROL

The chief reason for this is undoubtedly found in its remarkable reliability of action.

A great many practitioners have expressed their appreciation of the palatability of Agarol, especially the complete absence of oily or greasy taste. Others have remarked on its gratifying freedom from any griping, discomfort or anal leakage. But report after report has emphasized the uniform efficiency with which it has produced the results desired.

A moment's consideration of the composition of Agarol—with its carefully balanced proportions of pure mineral oil, agar-agar and phenolphthalein—followed by a practical clinical test, will convince the most critical practitioner that here is no ordinary laxative, but a rational physiologic corrective that offers far-reaching possibilities in restoring regularity of the bowels.

A generous trial quantity free upon request.

WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmaceutists since 1856
113-123 WEST 18th STREET - NEW YORK CITY

FOOT ILLS

are known today to be the frequent cause of much distress and discomfort as well as a fruitful source of many remote and often obscure symptoms. Authorities recognize that faulty footwear, especially hard, unyielding and otherwise improper heels, are among the most prolific causes of foot ailments. It has been conclusively proven, therefore, that

O'Sullivan's Heels

with their gratifying resiliency and cushion-like action, act not only to prevent these troubles, but will give pronounced aid in exercising and strengthening the foot muscles and overcoming the weakened and strained condition that is so often the forerunner of more serious derangements.

Medical men are realizing more and more every day the definite value of O'Sullivan's Heels, not alone in the prevention of foot ills, but in their rational treatment.

The use of O'Sullivan's Heels spells comfort and foot health.

O'SULLIVAN RUBBER CO., Inc. **New York City**

Important Information

WITH a feeling of certain responsibility to the medical profession, we would notify all members thereof that in order to conform with somewhat recent Federal Legislation, we have ceased supplying Glykeron with Diacetyl Morphine as a constituent and that all of the product of this original composition, now obtainable is only that to be found in the hands of the wholesale and retail druggists.

Glykeron, however, has not been discontinued, but the narcotic constituent has been changed and the Glykeron now distributed direct from our laboratories, contains one grain Codeine Phosphate in each fluid ounce instead of Diacetyl Morphine.

"Diabetes, Diabesan and a Grateful Patient"

Point Pleasant Beach, N. J.,
September 29, 1925.

Dr. Werner.
My dear Friend:—

I can call you friend as "Amicus certus in re incerta cernitur."

When I left the hospital last May after the "Allen Starvation Treatment" I weighed only 106 lbs., very weak and debilitated with glycosuria and glycemia, very much discouraged and melancholy. Dr. Shoub wrote me that he had seen very good results from the "Rational Treatment of Diabetes," by Dr. Werner, President of the Solosan Company of Morristown, N. J. With much misgiving I began your treatment about July last.

I want to congratulate you on my condition. I now weigh 122 lbs., very good color in my face, no sugar in the urine, very little blood sugar, no diacetic acid, no acetone.

I feel much stronger and do not tire easily, as before. I sleep better and not so nervous. I feel better and clinically proven to be better.

A grateful patient,
REV. JOSEPH V. SWEENEY.

Mothers—now have no excuse

for not serving hot oats porridge

WOMEN who used to protest when you said, "serve hot oats porridge," because oats took so long to cook, now can raise no objection.

Just tell them to get Quick Quaker, which cooks in 3 *to* 5 *minutes*! It's just the same as Quaker Oats—rich, luscious oats. But the flakes have been rolled extra thin and partially cooked.

It's a new Quaker process.

Result? The best of all breakfast dishes, ready as soon as the coffee. Children sent off to school and men to work stimulated and satisfied. Energy, endurance and vitality sustained by the ideal food-fuel.

Quick Quaker is a blessing to busy mothers, and to children who need building-up. Doctors and dieticians are quick to recommend it, for it solves the problem of serving quick yet hearty breakfasts.

Standard full size and weight packages—
Medium: **1¼ pounds;**
Large: **3 pounds, 7 oz.**

Quick Quaker

Cooks in 3 to 5 minutes

Producing Loeser's Intravenous Solutions, the Standardized, Certified Solutions

The Management of an Infant's Diet

Malnutrition, Marasmus, Infantile Atrophy, Athrepsia

Mellin's Food	**8 level tablespoonfuls**
Skimmed Milk (1% fat)	**9 fluidounces**
Water	**15 fluidounces**

This mixture contains 56.61 grams of carbohydrates, thus supplying material that is utilized rapidly for heat and energy. The predominating carbohydrate is MALTOSE, which has the highest point of assimilation of any of the sugars, is immediately available as fuel and may be safely given in comparatively large amounts. The daily intake of protein from the employment of this formula is 15.54 grams, an amount calculated to be sufficient to replace depleted tissues and to provide for new growth. There is present in the mixture 4.32 grams of salts for replenishing inorganic elements.

The suggested modification furnishes nutrition in keeping with the character and amount of food elements best adapted to the particular demands of infants in an extreme state of emaciation and serves well as a starting point in attempting to meet the nutritive requirements of these undernourished babies.

GLAND PRODUCTS

Specification the Surest Guaranty of Clinical Results

UNIFORM methods cannot be employed for the extraction and desiccation of different glands. The best method of handling each gland must be determined by experiment, the processes of manufacture in each instance being designed with reference to the peculiarities of the particular gland in question to yield a satisfactory finished preparation.

The identity of the gland is of first importance, and this is particularly true of parathyroids. It is very easy to confuse other glands with the true parathyroid glands.

All glands employed by us must be normal. They are all examined for evidence of disease. Before desiccation, all non-glandular matter is removed; this procedure reduces the weight of the glands as they reach us, often to a large extent.

The greatest care is also exercised to select and dissect only that part of the gland which is required in the manufacture of the product, such as the corpus luteum, from ovaries, the anterior lobe from the pituitary body, ovarian residue from ovaries and the posterior lobe of the pituitary. Some glands, such as the thyroid, thymus, pineal, etc., are utilized in entirety. Where fatty tissue is present in excessive quantity it is removed by solvents in a way to prevent injury to the active gland substance.

To still further increase the activity of our gland products we pass the desiccated material, after it has been finely powdered, through sieves to get rid of the remnants of inactive fibrous and connective tissue.

Our gland products therefore represent only the useful parts of the raw material we receive, and for this among other reasons contain a maximum amount of the therapeutically active portion of the glands.

Only by specifying our gland products—by adding to his prescription for gland products the designation "P. D. & Co.," can the benefits of the careful work we do be secured by the prescriber.

We will gladly send literature on the gland products in which you are interested.

MERRELL

ADMINISTERED orally, Fibrogen, in 3 c. c. dosage, controls hemorrhage in every part of the body within 15 minutes.

Used 15 minutes before operating, Fibrogen Oral not only prevents hemorrhage, but also assures the surgeon of an almost bloodless field.

Fibrogen, or *tissue fibrinogen*, is normally present, as a definite chemical compound, in all body tissues and is an essential element in clot formation.

Fibrogen Subcutaneous is also available, in ampoule form, and is equally effective. Its effect is slower, but more prolonged, lasting from 8 to 10 hours.

THE WM S. MERRELL COMPANY FOUNDED 1828 CINCINNATI, U.S.A.

LIQUID PEPTONOIDS WITH CREOSOTE

Combines the active and known therapeutic qualities of creosote and guaiacol with the nutritive properties of Liquid Peptonoids and is accordingly a thoroughly dependable product of definite quantities and recognized qualities as shown by the formula:

Each tablespoonful represents

Alcohol (By Volume)	12%
Pure Beechwood Creosote	2 min.
Guaiacol	1 min.
Proteins (Peptones and Propeptones)	5.25%
Lactose and Dextrose	11.3%
Cane Sugar	2.5%
Mineral Constituents (Ash)	0.95%

It acts as a bronchial sedative and expectorant, exhibiting a peculiar ability to relieve *Bronchitis—acute or chronic.* It checks as well a persistent winter cough and without harsh or untoward effect. It is agreeable to the palate and acceptable to the stomach—with merit as an intestinal antiseptic. Supplied in 12 oz. bottles.

Samples on request

YONKERS, NEW YORK

IODIN

that will give Iodin results without the usual Iodin disturbances

Organidin—Wampole

Organic Iodin—Iodin organically combined

Physicians are prescribing Organidin actively and reporting splendid results in a wide range of cases, including abnormally high blood-pressure, Asthmas, Arthritis, Goitre and enlarged glands, certain manifestations of Tuberculosis, obstinate skin diseases and a variety of conditions that have a history of latent syphilitic infection.

Price $8.00 per dozen one-ounce bottles
(one ounce is an ordinary three weeks' treatment).

Prepared Solely by

HENRY K. WAMPOLE & COMPANY

Incorporated

Manufacturing Pharmacists **Philadelphia, U. S. A.**

Physicians wanted a PRODUCT

Ever since the acceptance of mineral oil as an intestinal lubricant, physicians have felt the need of a preparation that would be more than a physiological catalyst. They have wanted a palatable petroleum product containing a PROTEOLYTIC catalyst—an intestinal digestive—of proved efficiency and therapeutic value.

We made it!

After exhaustive experimentation and clinical test, we perfected such a preparation—one that is winning the endorsement of physicians everywhere. This product is a scientific union of liquid petrolatum and aromatized rhubarb—to which has been added a pancreatic extract taken from the entire gland, and phenolphthalein (0.03 Grm. to each 4.0), (as per McWalters on phenolphthalein clinical therapy).

In constipation, auto-intoxication, absorption, etc., physicians are finding Rayminol a distinct advance in catalytic therapy. It is indicated wherever normal functioning of the intestinal tract is desired from a CORRECTIVE rather than a palliative standpoint.

Prescribe

RAYMINOL
(*Doyle*)
for Constipation

We shall be glad to send physicians a trial bottle of Rayminol. Your request brings it.

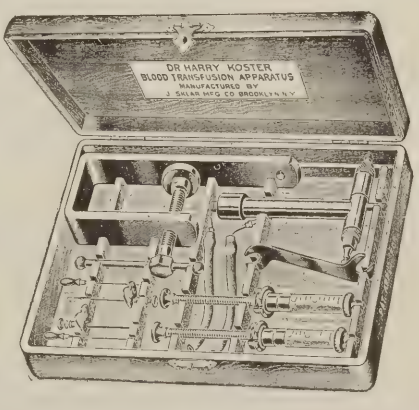
The New Method of Blood Transfusion

So simplified that this operation now becomes one of minor procedure

THE difficulties hitherto associated with the transfusing of blood have been eliminated in the new method perfected by Dr. Harry Koster of Brooklyn, N. Y. Its simplicity and effectiveness recommend it to every practitioner.

By this new method 1,000 c.c. is transferred in less than eight minutes, no blood is lost, the operation is not subject to mistakes and reactions do not occur.

The detailed advantages of this apparatus are contained in a paper read by Dr. Koster before one of the Medical Associations. Send for a copy, using the coupon which is printed for your convenience.



You are invited to inspect this apparatus at your regular surgical supply dealer

Price in wood case $35.00; price in sterilizable metal case $40.00

HEADACHES

due to cerebral congestion can be controlled with gratifying promptness by the use of

Peacock's Bromides

This dependable sedative quickly allays cerebral excitability, relaxes nerve tension, and reduces the resulting congestion. It is invaluable, therefore, as a safe and palatable anti-spasmodic and anodyne in the treatment of functional circulatory derangements, especially those of the female involving the utero-ovarian blood supply.

Here are 6 *Forms of Mercury*

In Ampoules for the Treatment of Syphilis

A FORM TO SUIT INDIVIDUAL PREFERENCE. For nearly five centuries, mercury has stood pre-eminent as an antileutic agent. The important consideration is to administer the product in therapeutic doses. The form for administration becomes a matter of personal preference, and the ampoules offered by Swan-Myers Company afford a variety of forms sufficient to suit the ideas of most physicians. Select the Mercury ampoule which you prefer and order a package from your dealer. If he cannot supply you, order direct.

COUNCIL PASSED

FOR INTRAMUSCULAR ADMINISTRATION

Mercuric Potassium Iodide, 0.015 Gm. (1/4 gr.) 1 cc. ampoule, No. 33.
Mercury Benzoate, 2% solution—1 cc. ampoule, No. 28.
Mercury Biniodide, 0.01 Gm. (1/6 gr.) 1 cc. ampoule, No. 22.
Mercury Salicylate, 0.065 Gm. (1 gr.) 1cc. ampoule, No. 9.
Mercury Salicylate, 0.097 Gm. (11/2 grs.) 1 cc. ampoule, No. 10.
Mercury Succinimide, 0.01 Gm. (1/6 gr.) 1 cc. ampoule, No. 67.

FOR INTRAVENOUS USE

Mercury Oxycyanide, 0.008 Gm. (1/8 gr.) 5 cc. ampoule, No. 43
Mercury Oxycyanide, 0.01 Gm. (1/6 gr.) 5 cc. ampoule, No. 51.

To Overcome Constipation

with more than temporary effect, it is essential to promote the physiologic processes of the bowel. Owing to their composition

PRUNOIDS

are particularly capable of this, and thus act not merely as an eliminant but exert a real tonic influence on the intestinal muscles and glands. As a consequence, they are not only potent, but persistent in effect, and free from iniquities of ordinary laxatives.

Kellogg's ALL-BRAN

Opiates Are Unnecessary

PHENALGIN

has made them so, and given to the practitioner a better, safer, and more effectual means of relieving and controlling pain.

In addition to its anodyne efficiency, **Phenalgin** has the following noteworthy advantages —

1 -- Does not create a habit.
2 -- Does not disturb the digestion.
3 -- Does not suppress the secretions.
4 -- Does not retard bowel action.
5 -- Is not subject to Government restrictions.
6 -- Requires no filling out of blanks or keeping of special records.

Is it surprising, therefore, that **Phenalgin** has so largely taken the place of the opiates in the treatment of **headache, neuralgia, rheumatism, painful menstruation, lumbago,** and so many other painful affections?

DIABAN DIABETIC FLOUR

Physicians welcome the facility with which it is now possible to maintain synchronously the patient's nourishment and control the sugar secretion through the employment of a low carbohydrate flour.

Diaban muffins are utilizable with or without insulin in mild or severe types of the malady, and their delicious flavor is a boon to the patient that hitherto he has been denied.

One Diaban muffin contains less than one third as much carbohydrates and only twice as much protein as found in an equal quantity of wheat bread. One package of Diaban Flour (2 days supply) makes 12 muffins, each muffin containing 5.0 grams carbohydrates, 5.3 grams protein, 3.3 grams fat, 71 calories.

Analysis and directions on every package. Diaban Flour is uniform and analysis always dependable. Physician's circular sent upon request.

INFANT DIET MEAD'S MATERIALS

Feeding Babies in Winter

Neither cow's milk nor breast-milk contains sufficient antirachitic power to protect all infants from RICKETS.

Also—during the winter months, babies are usually not exposed to a sufficient amount of sunlight to prevent RICKETS.

The prescribing of MEAD'S STANDARDIZED AND BIOLOGICALLY-ASSAYED COD LIVER OIL by the physician is one of the most valuable safeguards against RICKETS.

MEAD'S is not an ordinary COD LIVER OIL. Every step in its preparation, from the time the fish are caught until the oil is finally tested and bottled, is scientifically controlled. Its purity and potency is guaranteed.

Samples and literature furnished immediately on request.

The Mead Policy

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians.

MEAD JOHNSON & COMPANY, Evansville, Indiana, U. S. A.
Manufacturers of Infant Diet Materials

Why Prescribe It for Infants Deprived of Breast Milk?

Synthetic Milk Adapted to Breast Milk

1. **It gives excellent nutritional results in most cases.** That is the experience of thousands of physicians.
2. **No modification is necessary for normal, full term infants**—it is possible to give it, in the same strength, to infants from birth to two years of age. Only the total quantity is increased, as the infant's caloric requirements increase.
3. **It prevents rickets and spasmophilia**—the S. M. A. fat contains an adequate amount of cod liver oil. In addition, the kind of food constituents and their correlation in S. M. A. also play a role in the prevention of rickets and spasmophilia.
4. **It is easy for the physician to prescribe**—no complicated formulæ to remember.
5. **It is simple for the mother to prepare**—just add boiled water..

We believe that once you have tried S. M. A. you will fully appreciate these advantages. Write for literature and a liberal trial package.

Fine Products for the Infant's Diet

Unlucky 13

Unlucky for some people, perhaps, but *not for your anemic patient* when you prescribe

Hemoglobin Co. (Harrower)

—No. 13 on our list of pluriglandular formulas.

This excellent combination embodies *nuclein,* for its leucocyte-stimulating effect; *spleen,* because it prevents mineral loss; and *hemoglobin,* a non-constipating, easily assimilated iron. Remember it!

Hemoglobin Co. (Harrower)
Sig. 1 sanitablet q. i. d.

Note: In particularly severe and stubborn cases supplement the sanitablet formula with three intramuscular 1-mil injections a week of Sol. Hemo-Medullary Co. (Harrower). This solution combines hemoglobin and red bone-marrow of high quality. One grain of the desiccated red bone-marrow used in this solution represents 25 grains of fresh red bone-marrow, obtained from approximately 7500 grains of small, round calf bones.
